External Environment (page 17) Documentation on the auditing feature available with MongoDB Enterprise.

Security Tutorials (page 18) Tutorials for enabling and configuring security features for MongoDB.

Network Security Tutorials (page 19) Ensure that the underlying network configuration supports a secure operating environment for MongoDB deployments, and appropriately limits access to MongoDB deployments.

Authentication Tutorials (page 39) These tutorials describe procedures relevant for the configuration, operation, and maintenance of MongoDB’s access control system.

User and Role Management Tutorials (page 66) MongoDB’s access control system provides a flexible role-based access control system that you can use to limit access to MongoDB deployments. The tutorials in this section describe the configuration and setup of the authorization system.

Continue reading from Security Tutorials (page 18) for additional tutorials that address the use and management of secure MongoDB deployments.

Create a Vulnerability Report (page 83) Report a vulnerability in MongoDB.

Security Reference (page 84) Reference for security related functions.

Security Checklist (page 111) A high level overview of global security consideration for administrators of MongoDB deployments. Use this checklist if you are new to deploying MongoDB in production and want to implement high quality security practices.

1 Security Introduction

Maintaining a secure MongoDB deployment requires administrators to implement controls to ensure that users and applications have access to only the data that they require. MongoDB provides features that allow administrators to implement these controls and restrictions for any MongoDB deployment.

If you are already familiar with security and MongoDB security practices, consider the Security Checklist (page 111) for a collection of recommended actions to protect a MongoDB deployment.

1.1 Authentication

Before gaining access to a system all clients should identify themselves to MongoDB. This ensures that no client can access the data stored in MongoDB without being explicitly allowed.

MongoDB supports a number of authentication mechanisms (page 6) that clients can use to verify their identity. MongoDB supports two mechanisms: a password-based challenge and response protocol and x.509 certificates. Additionally, MongoDB Enterprise\(^1\) also provides support for LDAP proxy authentication (page 8) and Kerberos authentication (page 8).

See Authentication (page 6) for more information.

\(^1\)http://www.mongodb.com/products/mongodb-enterprise?jmp=docs
1.2 Role Based Access Control

Access control, i.e. authorization (page 14), determines a user’s access to resources and operations. Clients should only be able to perform the operations required to fulfill their approved functions. This is the “principle of least privilege” and limits the potential risk of a compromised application.

MongoDB’s role-based access control system allows administrators to control all access and ensure that all granted access applies as narrowly as possible. MongoDB does not enable authorization by default. When you enable authorization (page 14), MongoDB will require authentication for all connections.

When authorization is enabled, MongoDB controls a user’s access through the roles assigned to the user. A role consists of a set of privileges, where a privilege consists of actions, or a set of operations, and a resource upon which the actions are allowed.

Users may have one or more role that describes their access. MongoDB provides several built-in roles (page 85) and users can construct specific roles tailored to clients’ actual requirements.

See Authorization (page 14) for more information.

1.3 Auditing

Auditing provides administrators with the ability to verify that the implemented security policies are controlling activity in the system. Retaining audit information ensures that administrators have enough information to perform forensic investigations and comply with regulations and polices that require audit data.

See Auditing (page 16) for more information.

1.4 Encryption

Transport Encryption

You can use TLS/SSL (Transport Layer Security/Secure Sockets Layer) to encrypt all of MongoDB’s network traffic. TLS/SSL ensures that MongoDB network traffic is only readable by the intended client.

See Configure mongod and mongos for TLS/SSL (page 26) for more information.

Encryption at Rest

There are two broad classes of approaches to encrypting data at rest with MongoDB: Application Level Encryption (page 4) and Storage Encryption (page 4). You can use these solutions together or independently. Application Level Encryption provides encryption on a per-field or per-document basis within the application layer. To encrypt document or field level data, write custom encryption and decryption routines or use a commercial solution such as the Vormetric Data Security Platform\(^2\). Storage Encryption encrypts all MongoDB data on the storage or operating system to ensure that only authorized processes can access protected data. A number of third-party libraries can integrate with the operating system to provide transparent disk-level encryption. For example:

- **Linux Unified Key Setup (LUKS)** LUKS is available for most Linux distributions. For configuration explanation, see the LUKS documentation from Red Hat\(^3\).

- **IBM Guardium Data Encryption** IBM Guardium Data Encryption\(^4\) provides support for disk-level encryption for Linux and Windows operating systems.

• **Vormetric Data Security Platform** The Vormetric Data Security Platform\(^5\) provides disk and file-level encryption in addition to application level encryption.

• **Bitlocker Drive Encryption** Bitlocker Drive Encryption\(^6\) is a feature available on Windows Server 2008 and 2012 that provides disk encryption.

Properly configured disk encryption, when used alongside good security policies that protect relevant accounts, passwords, and encryption keys, can help ensure compliance with standards, including HIPAA, PCI-DSS, and FERPA.

### 1.5 Hardening Deployments and Environments

In addition to implementing controls within MongoDB, you should also place controls around MongoDB to reduce the risk exposure of the entire MongoDB system. This is a defense in depth strategy.

Hardening MongoDB extends the ideas of least privilege, auditing, and encryption outside of MongoDB. Reducing risk includes: configuring the network rules to ensure that only trusted hosts have access to MongoDB, and that the MongoDB processes only have access to the parts of the filesystem required for operation.

\(^7\) [https://www.mongodb.com/blog/post/making-hipaa-compliant-applications-mongodb?jmp=docs](https://www.mongodb.com/blog/post/making-hipaa-compliant-applications-mongodb?jmp=docs)

Authentication

Authentication is the process of verifying the identity of a client. When access control, i.e. authorization (page 14), is enabled, MongoDB requires all clients to authenticate themselves first in order to determine the access for the client.

Although authentication and authorization (page 14) are closely connected, authentication is distinct from authorization. Authentication verifies the identity of a user; authorization determines the verified user’s access to resources and operations.

MongoDB supports a number of authentication mechanisms (page 6) that clients can use to verify their identity. These mechanisms allow MongoDB to integrate into your existing authentication system. See Authentication Mechanisms (page 6) for details.

In addition to verifying the identity of a client, MongoDB can require members of replica sets and sharded clusters to authenticate their membership (page 8) to their respective replica set or sharded cluster. See Authentication Between MongoDB Instances (page 8) for more information.

Client Users

To authenticate a client in MongoDB, you must add a corresponding user to MongoDB. When adding a user, you create the user in a specific database. Together, the user’s name and database serve as a unique identifier for that user. That is, if two users have the same name but are created in different databases, they are two separate users. To authenticate, the client must authenticate the user against the user’s database. For instance, if using the mongo shell as a client, you can specify the database for the user with the --authenticationDatabase option.

To add and manage user information, MongoDB provides the db.createUser() method as well as other user management methods. For examples of user management in MongoDB, see Manage User and Roles (page 69).

MongoDB stores all user information, including name (page 96), password (page 96), and the user’s database (page 96), in the system.users (page 96) collection in the admin database.

Authentication Mechanisms

Changed in version 3.0.

MongoDB supports multiple authentication mechanisms. MongoDB’s default authentication method is a challenge and response mechanism (SCRAM-SHA-1) (page 6). Previously, MongoDB used MongoDB Challenge and Response (MONGODB-CR) (page 7) as the default.

MongoDB also supports x509 certificate authentication (page 8), LDAP proxy authentication (page 8), and Kerberos authentication (page 8).

This section introduces the mechanisms available in MongoDB.

To specify the authentication mechanism to use, see authenticationMechanisms.

SCRAM–SHA–1 Authentication  New in version 3.0.

SCRAM–SHA–1 is an IETF standard, RFC 5802\(^{10}\), that defines best practice methods for implementation of challenge-response mechanisms for authenticating users with passwords.

SCRAM–SHA–1 verifies supplied user credentials against the user’s name (page 96), password (page 96) and database (page 96). The user’s database is the database where the user was created, and the user’s database and the user’s name together serves to identify the user.

\(^{10}\text{https://tools.ietf.org/html/rfc5802}\)
Note: A driver upgrade is necessary to use the SCRAM-SHA-1 authentication mechanism if your current driver version does not support SCRAM-SHA-1. See required driver versions for details.

See also:
- Blog Post: Improved Password-Based Authentication in MongoDB 3.0: SCRAM Explained (Part 1)\(^1\)
- Blog Post: Improved Password-Based Authentication in MongoDB 3.0: SCRAM Explained (Part 2)\(^2\)

**SCRAM-SHA-1 Advantages** MongoDB’s implementation of SCRAM-SHA-1 represents an improvement in security over the previously-used MONGODB-CR, providing:

- A tunable work factor (iterationCount),
- Per-user random salts rather than server-wide salts,
- A cryptographically stronger hash function (SHA-1 rather than MD5), and
- Authentication of the server to the client as well as the client to the server.

**SCRAM-SHA-1 and Existing User Credentials** SCRAM-SHA-1 is the default mechanism for MongoDB versions beginning with the 3.0 series. However, if you are upgrading a MongoDB 2.6 instances that already have users credentials, MongoDB will continue to use MONGODB-CR for challenge-response authentication until you upgrade the authentication schema. Even when using the MONGODB-CR authentication mechanism, clients and drivers that support MongoDB 3.0 features (see compatibility-driver-versions) will use the SCRAM communication protocol.

For details on upgrading the authentication schema model to SCRAM-SHA-1, see http://docs.mongodb.org/manual/release-notes/3.0-scram.

| Warning: The procedure to upgrade to SCRAM-SHA-1 discards the MONGODB-CR credentials used by 2.6. As such, the procedure is irreversible, short of restoring from backups. The procedure also disables MONGODB-CR as an authentication mechanism. |

**MONGODB-CR Authentication** MONGODB-CR is a challenge-response mechanism that authenticates users through passwords.

Changed in version 3.0: As of version 3.0, MongoDB no longer defaults to MONGODB-CR and instead uses SCRAM-SHA-1 as the default authentication mechanism.

MONGODB-CR verifies supplied user credentials against the user’s name (page 96), password (page 96) and database (page 96). The user’s database is the database where the user was created, and the user’s database and the user’s name together serve to identify the user.

Using key files, you can also use MONGODB-CR authentication for the *internal member authentication* (page 8) of replica set members and sharded cluster members. The contents of the key files serve as the shared password for the members. You must store the key file on each mongod or mongos instance for that replica set or sharded cluster. The content of the key file is arbitrary but must be the same on all mongod and mongos instances that connect to each other.

See *Generate a Key File* (page 62) for instructions on generating a key file and turning on key file authentication for members.

\(^1\)https://www.mongodb.com/blog/post/improved-password-based-authentication-mongodb-30-scram-explained-part-1?jmp=docs
x.509 Certificate Authentication  New in version 2.6.

MongoDB supports x.509 certificate authentication for use with a secure TLS/SSL connection (page 26).

To authenticate to servers, clients can use x.509 certificates instead of usernames and passwords. See Client x.509 Certificate (page 44) for more information.

For membership authentication, members of sharded clusters and replica sets can use x.509 certificates instead of key files. See Use x.509 Certificate for Membership Authentication (page 46) for more information.

Kerberos Authentication  MongoDB Enterprise supports authentication using a Kerberos service. Kerberos is an industry standard authentication protocol for large client/server systems.

To use MongoDB with Kerberos, you must have a properly configured Kerberos deployment, configured Kerberos service principals (page 12) for MongoDB, and added Kerberos user principal (page 12) to MongoDB.

See Kerberos Authentication (page 11) for more information on Kerberos and MongoDB. To configure MongoDB to use Kerberos authentication, see Configure MongoDB with Kerberos Authentication on Linux (page 55) and Configure MongoDB with Kerberos Authentication on Windows (page 59).

LDAP Proxy Authority Authentication  MongoDB Enterprise supports proxy authentication through a Lightweight Directory Access Protocol (LDAP) service. See Authenticate Using SASL and LDAP with OpenLDAP (page 52) and Authenticate Using SASL and LDAP with ActiveDirectory (page 49).

MongoDB Enterprise for Windows does not include LDAP support for authentication. However, MongoDB Enterprise for Linux supports using LDAP authentication with an ActiveDirectory server.

MongoDB does not support LDAP authentication in mixed sharded cluster deployments that contain both version 2.4 and version 2.6 shards.

Authentication Behavior

Client Authentication  Clients can authenticate using the challenge and response (page 7), x.509 (page 8), LDAP Proxy (page 8) and Kerberos (page 8) mechanisms.

Each client connection should authenticate as exactly one user. If a client authenticates to a database as one user and later authenticates to the same database as a different user, the second authentication invalidates the first. While clients can authenticate as multiple users if the users are defined on different databases, we recommend authenticating as one user at a time, providing the user with appropriate privileges on the databases required by the user.

See Authenticate to a MongoDB Instance or Cluster (page 61) for more information.

Authentication Between MongoDB Instances  You can authenticate members of replica sets and sharded clusters. To authenticate members of a single MongoDB deployment to each other, MongoDB can use the keyFile and x.509 (page 8) mechanisms. Using keyFile authentication for members also enables authorization.

Always run replica sets and sharded clusters in a trusted networking environment. Ensure that the network permits only trusted traffic to reach each mongod and mongos instance.

Use your environment’s firewall and network routing to ensure that traffic only from clients and other members can reach your mongod and mongos instances. If needed, use virtual private networks (VPNs) to ensure secure connections over wide area networks (WANs).

Always ensure that:

14http://www.mongodb.com/products/mongodb-enterprise?jmp=docs
Your network configuration will allow every member of the replica set or sharded cluster to contact every other member.

If you use MongoDB’s authentication system to limit access to your infrastructure, ensure that you configure a keyFile on all members to permit authentication.

See *Generate a Key File* (page 62) for instructions on generating a key file and turning on key file authentication for members. For an example of using key files for sharded cluster authentication, see *Enable Authentication in a Sharded Cluster* (page 41).

**Authentication on Sharded Clusters**  
In sharded clusters, applications authenticate to directly to mongos instances, using credentials stored in the admin database of the config servers. The shards in the sharded cluster also have credentials, and clients can authenticate directly to the shards to perform maintenance directly on the shards. In general, applications and clients should connect to the sharded cluster through the mongos.

Changed in version 2.6: Previously, the credentials for authenticating to a database on a cluster resided on the primary shard for that database.

Some maintenance operations, such as cleanupOrphaned, compact, rs.reconfig(), require direct connections to specific shards in a sharded cluster. To perform these operations with authentication enabled, you must connect directly to the shard and authenticate as a shard local administrative user. To create a shard local administrative user, connect directly to the shard and create the user. MongoDB stores shard local users in the admin database of the shard itself. These shard local users are completely independent from the users added to the sharded cluster via mongos. Shard local users are local to the shard and are inaccessible by mongos. Direct connections to a shard should only be for shard-specific maintenance and configuration.

**Localhost Exception**  
The localhost exception allows you to enable authorization before creating the first user in the system. When active, the localhost exception allows connections from the localhost interface to create the first user on the admin database. The exception applies only when there are no users created in the MongoDB instance.

Changed in version 3.0: The localhost exception changed so that these connections only have access to create the first user on the admin database. In previous versions, connections that gained access using the localhost exception had unrestricted access to the MongoDB instance.

If you use the localhost exception when deploying a new MongoDB system, the first user you create must be in the admin database with privileges to create other users, such as a user with the userAdmin (page 87) or userAdminAnyDatabase (page 92) role. See *Enable Client Access Control* (page 40) and *Create a User Administrator* (page 67) for more information.

In the case of a sharded cluster, the localhost exception applies to each shard individually as well as to the cluster as a whole. Once you create a sharded cluster and add an administrator to the mongos instance, you must still prevent unauthorized access to the individual shards. Follow one of the following steps for each shard in your cluster:

- Create an administrative user, or
- Disable the localhost exception at startup. To disable the localhost exception, use setParameter in your configuration file, or --setParameter on the command line to set the enableLocalhostAuthBypass parameter to 0.

**Network Exposure and Security**

By default, MongoDB programs (i.e. mongos and mongod) will bind to all available network interfaces (i.e. IP addresses) on a system.

This page outlines various runtime options that allow you to limit access to MongoDB programs.
**Configuration Options**

You can limit the network exposure with the following `mongod` and `mongos` configuration options: `enabled`, `net.http.RESTInterfaceEnabled`, `bindIp`, and `port`. You can use a configuration file to specify these settings.

**nohttpinterface**  The `enabled` setting for `mongod` and `mongos` instances disables the “home” status page.

Changed in version 2.6: The `mongod` and `mongos` instances run with the http interface disabled by default.

The status interface is read-only by default, and the default port for the status page is 28017. Authentication does not control or affect access to this interface.

**Warning:** Disable this interface for production deployments. If you enable this interface, you should only allow trusted clients to access this port. See *Firewalls* (page 11).

**rest**  The `net.http.RESTInterfaceEnabled` setting for `mongod` enables a fully interactive administrative REST interface, which is disabled by default. The `net.http.RESTInterfaceEnabled` configuration makes the http status interface, which is read-only by default, fully interactive. Use the `net.http.RESTInterfaceEnabled setting` with the `enabled` setting.

The REST interface does not support any authentication and you should always restrict access to this interface to only allow trusted clients to connect to this port.

You may also enable this interface on the command line as `mongod --rest --httpinterface`.

**Warning:** Disable this option for production deployments. If do you leave this interface enabled, you should only allow trusted clients to access this port.

**bind_ip**  The `bindIp` setting for `mongod` and `mongos` instances limits the network interfaces on which MongoDB programs will listen for incoming connections. You can also specify a number of interfaces by passing `bindIp` a comma separated list of IP addresses. You can use the `mongod --bind_ip` and `mongos --bind_ip` option on the command line at run time to limit the network accessibility of a MongoDB program.

**Important:** Make sure that your `mongod` and `mongos` instances are only accessible on trusted networks. If your system has more than one network interface, bind MongoDB programs to the private or internal network interface.

**port**  The `port` setting for `mongod` and `mongos` instances changes the main port on which the `mongod` or `mongos` instance listens for connections. The default port is 27017. Changing the port does not meaningfully reduce risk or limit exposure. You may also specify this option on the command line as `mongod --port` or `mongos --port`. Setting `port` also indirectly sets the port for the HTTP status interface, which is always available on the port numbered 1000 greater than the primary `mongod` port.

Only allow trusted clients to connect to the port for the `mongod` and `mongos` instances. See *Firewalls* (page 11).

See also `configuration-security` and *Default MongoDB Port* (page 104).

---

15 Starting in version 2.6, http interface is disabled by default.
Firewalls

Firewalls allow administrators to filter and control access to a system by providing granular control over what network communications. For administrators of MongoDB, the following capabilities are important: limiting incoming traffic on a specific port to specific systems, and limiting incoming traffic from untrusted hosts.

On Linux systems, the `iptables` interface provides access to the underlying `netfilter` firewall. On Windows systems, `netsh` command line interface provides access to the underlying Windows Firewall. For additional information about firewall configuration, see `Configure Linux iptables Firewall for MongoDB` (page 19) and `Configure Windows netsh Firewall for MongoDB` (page 23).

For best results and to minimize overall exposure, ensure that only traffic from trusted sources can reach `mongod` and `mongos` instances and that the `mongod` and `mongos` instances can only connect to trusted outputs.

See also:

For MongoDB deployments on Amazon’s web services, see the Amazon EC2\(^{16}\) page, which addresses Amazon’s Security Groups and other EC2-specific security features.

Virtual Private Networks

Virtual private networks, or VPNs, make it possible to link two networks over an encrypted and limited-access trusted network. Typically, MongoDB users who use VPNs use TLS/SSL rather than IPSEC VPNs for performance issues.

Depending on configuration and implementation, VPNs provide for certificate validation and a choice of encryption protocols, which requires a rigorous level of authentication and identification of all clients. Furthermore, because VPNs provide a secure tunnel, by using a VPN connection to control access to your MongoDB instance, you can prevent tampering and “man-in-the-middle” attacks.

Kerberos Authentication

New in version 2.4.

Overview

MongoDB Enterprise provides support for Kerberos authentication of MongoDB clients to `mongod` and `mongos`. Kerberos is an industry standard authentication protocol for large client/server systems. Kerberos allows MongoDB and applications to take advantage of existing authentication infrastructure and processes.

Kerberos Components and MongoDB

Principals  In a Kerberos-based system, every participant in the authenticated communication is known as a “principal”, and every principal must have a unique name.

Principals belong to administrative units called `realms`. For each realm, the Kerberos Key Distribution Center (KDC) maintains a database of the realm’s principal and the principals’ associated “secret keys”.

For a client-server authentication, the client requests from the KDC a “ticket” for access to a specific asset. KDC uses the client’s secret and the server’s secret to construct the ticket which allows the client and server to mutually authenticate each other, while keeping the secrets hidden.

For the configuration of MongoDB for Kerberos support, two kinds of principal names are of interest: `user principals` (page 12) and `service principals` (page 12).

\(^{16}\)https://docs.mongodb.org/ecosystem/platforms/amazon-ec2
User Principal  To authenticate using Kerberos, you must add the Kerberos user principals to MongoDB to the $external database. User principal names have the form:

<username>@<KERBEROS REALM>

For every user you want to authenticate using Kerberos, you must create a corresponding user in MongoDB in the $external database.

For examples of adding a user to MongoDB as well as authenticating as that user, see Configure MongoDB with Kerberos Authentication on Linux (page 55) and Configure MongoDB with Kerberos Authentication on Windows (page 59).

See also:

User and Role Management Tutorials (page 66) for general information regarding creating and managing users in MongoDB.

Service Principal  Every MongoDB mongod and mongos instance (or mongod.exe or mongos.exe on Windows) must have an associated service principal. Service principal names have the form:

<service>/<fully qualified domain name>@<KERBEROS REALM>

For MongoDB, the <service> defaults to mongodb. For example, if m1.example.com is a MongoDB server, and example.com maintains the EXAMPLE.COM Kerberos realm, then m1 should have the service principal name mongodb/m1.example.com@EXAMPLE.COM.

To specify a different value for <service>, use serviceName during the start up of mongod or mongos (or mongod.exe or mongos.exe). mongo shell or other clients may also specify a different service principal name using serviceName.

Service principal names must be reachable over the network using the fully qualified domain name (FQDN) part of its service principal name.

By default, Kerberos attempts to identify hosts using the /etc/kerb5.conf file before using DNS to resolve hosts.

On Windows, if running MongoDB as a service, see Assign Service Principal Name to MongoDB Windows Service (page 61).

Linux Keytab Files  Linux systems can store Kerberos authentication keys for a service principal (page 12) in keytab files. Each Kerberized mongod and mongos instance running on Linux must have access to a keytab file containing keys for its service principal (page 12).

To keep keytab files secure, use file permissions that restrict access to only the user that runs the mongod or mongos process.

Tickets  On Linux, MongoDB clients can use Kerberos’s kinit program to initialize a credential cache for authenticating the user principal to servers.

Windows Active Directory  Unlike on Linux systems, mongod and mongos instances running on Windows do not require access to keytab files. Instead, the mongod and mongos instances read their server credentials from a credential store specific to the operating system.

However, from the Windows Active Directory, you can export a keytab file for use on Linux systems. See Ktpass\(^\text{17}\) for more information.

Authenticate With Kerberos  To configure MongoDB for Kerberos support and authenticate, see Configure MongoDB with Kerberos Authentication on Linux (page 55) and Configure MongoDB with Kerberos Authentication on Windows (page 59).

Operational Considerations

The HTTP Console  The MongoDB HTTP Console\(^{18}\) interface does not support Kerberos authentication.

DNS  Each host that runs a mongod or mongos instance must have both A and PTR DNS records to provide forward and reverse lookup.

Without A and PTR DNS records, the host cannot resolve the components of the Kerberos domain or the Key Distribution Center (KDC).

System Time Synchronization  To successfully authenticate, the system time for each mongod and mongos instance must be within 5 minutes of the system time of the other hosts in the Kerberos infrastructure.

Kerberized MongoDB Environments

Driver Support  The following MongoDB drivers support Kerberos authentication:

- C\(^{19}\)
- C++\(^{20}\)
- Java\(^{21}\)
- C#\(^{22}\)
- Node.js\(^{23}\)
- PHP\(^{24}\)
- Python\(^{25}\)
- Ruby\(^{26}\)

Use with Additional MongoDB Authentication Mechanism  Although MongoDB supports the use of Kerberos authentication with other authentication mechanisms, only add the other mechanisms as necessary. See the Incorporate Additional Authentication Mechanisms section in Configure MongoDB with Kerberos Authentication on Linux (page 55) and Configure MongoDB with Kerberos Authentication on Windows (page 59) for details.

2.2 Access Control

These documents introduce and address concepts and strategies related to Role Based Access Control in MongoDB.

*Authorization* (page 14) Introduction to Role Based Access Control used in MongoDB

*Collection-Level Access Control* (page 16) Specify collection-level access control.

Authorization

MongoDB employs Role-Based Access Control (RBAC) to govern access to a MongoDB system. A user is granted one or more *roles* (page 14) that determine the user’s access to database resources and operations. Outside of role assignments, the user has no access to the system.

MongoDB does not enable authorization by default. You can enable authorization using the *--auth* or the *--keyFile* options, or if using a configuration file, with the *security.authorization* or the *security.keyFile* settings.

MongoDB provides *built-in roles* (page 85), each with a dedicated purpose for a common use case. Examples include the *read* (page 85), *readWrite* (page 86), *dbAdmin* (page 86), and *root* (page 93) roles.

Administrators also can create new roles and privileges to cater to operational needs. Administrators can assign privileges scoped as granularly as the collection level.

When granted a role, a user receives all the privileges of that role. A user can have several roles concurrently, in which case the user receives the union of all the privileges of the respective roles.

Roles

A role consists of privileges that pair resources with allowed operations. Each privilege is defined directly in the role or inherited from another role.

A role’s privileges apply to the database where the role is created. A role created on the *admin* database can include privileges that apply to all databases or to the *cluster* (page 98).

A user assigned a role receives all the privileges of that role. The user can have multiple roles and can have different roles on different databases.

Roles always grant privileges and never limit access. For example, if a user has both *read* (page 85) and *readWriteAnyDatabase* (page 92) roles on a database, the greater access prevails.

Privileges

A privilege consists of a specified resource and the actions permitted on the resource.

A privilege *resource* (page 97) is either a database, collection, set of collections, or the cluster. If the cluster, the affiliated actions affect the state of the system rather than a specific database or collection.

An *action* (page 99) is a command or method the user is allowed to perform on the resource. A resource can have multiple allowed actions. For available actions see *Permission Actions* (page 99).

\(^{28}\)http://docs.mongodb.org/ecosystem/tutorial/manage-red-hat-enterprise-linux-identity-management?jmp=docs
For example, a privilege that includes the update (page 99) action allows a user to modify existing documents on the resource. To additionally grant the user permission to create documents on the resource, the administrator would add the insert (page 99) action to the privilege.

For privilege syntax, see admin.system.roles.privileges (page 94).

Inherited Privileges  A role can include one or more existing roles in its definition, in which case the role inherits all the privileges of the included roles.

A role can inherit privileges from other roles in its database. A role created on the admin database can inherit privileges from roles in any database.

User-Defined Roles  New in version 2.6.

User administrators can create custom roles to ensure collection-level and command-level granularity and to adhere to the policy of least privilege. Administrators create and edit roles using the role management commands.

MongoDB scopes a user-defined role to the database in which it is created and uniquely identifies the role by the pairing of its name and its database. MongoDB stores the roles in the admin database’s system.roles (page 93) collection. Do not access this collection directly but instead use the role management commands to view and edit custom roles.

Collection-Level Access Control  By creating a role with privileges (page 14) that are scoped to a specific collection in a particular database, administrators can implement collection-level access control.

See Collection-Level Access Control (page 16) for more information.

Users

MongoDB stores user credentials in the protected admin.system.users. Use the user management methods to view and edit user credentials.

Role Assignment to Users  User administrators create the users that access the system’s databases. MongoDB’s user management commands let administrators create users and assign them roles.

MongoDB scopes a user to the database in which the user is created. MongoDB stores all user definitions in the admin database, no matter which database the user is scoped to. MongoDB stores users in the admin database’s system.users collection (page 96). Do not access this collection directly but instead use the user management commands.

The first role assigned in a database should be either userAdmin (page 87) or userAdminAnyDatabase (page 92). This user can then create all other users in the system. See Create a User Administrator (page 67).

Protect the User and Role Collections  MongoDB stores role and user data in the protected admin.system.roles and admin.system.users collections, which are only accessible using the user management methods.

If you disable access control, do not modify the admin.system.roles and admin.system.users collections using normal insert() and update() operations.

Additional Information

See the reference section for documentation of all built-in-roles (page 85) and all available privilege actions (page 99). Also consider the reference for the form of the resource documents (page 97).

To create users see the Create a User Administrator (page 67) and Manage User and Roles (page 69) tutorials.
Collection-Level Access Control

Collection-level access control allows administrators to grant users privileges that are scoped to specific collections. Administrators can implement collection-level access control through user-defined roles (page 15). By creating a role with privileges (page 14) that are scoped to a specific collection in a particular database, administrators can provision users with roles that grant privileges on a collection level.

Privileges and Scope

A privilege consists of actions (page 99) and the resources (page 97) upon which the actions are permissible; i.e. the resources define the scope of the actions for that privilege.

By specifying both the database and the collection in the resource document (page 97) for a privilege, administrator can limit the privilege actions just to a specific collection in a specific database. Each privilege action in a role can be scoped to a different collection.

For example, a user defined role can contain the following privileges:

```javascript
privileges: [
  { resource: { db: "products", collection: "orders" }, actions: [ "find" ] }
]
```

The first privilege scopes its actions to the inventory collection of the products database. The second privilege scopes its actions to the orders collection of the products database.

Additional Information

For more information on user-defined roles and MongoDB authorization model, see Authorization (page 14). For a tutorial on creating user-defined roles, see Manage User and Roles (page 69).

2.3 Auditing

New in version 2.6.

MongoDB Enterprise includes an auditing capability for mongod and mongos instances. The auditing facility allows administrators and users to track system activity for deployments with multiple users and applications. The auditing facility can write audit events to the console, the syslog, a JSON file, or a BSON file.

Audit Events and Filter

To enable auditing for MongoDB Enterprise, see Configure System Events Auditing (page 78).

Once enabled, the auditing system can record the following operations:

- schema (DDL),
- replica set,
- authentication and authorization, and
- general operations.
Audit Guarantee

The auditing system writes every audit event to an in-memory buffer of audit events. MongoDB writes this buffer to disk periodically. For events collected from any single connection, the events have a total order: if MongoDB writes one event to disk, the system guarantees that it has written all prior events for that connection to disk.

If an audit event entry corresponds to an operation that affects the durable state of the database, such as a modification to data, MongoDB will always write the audit event to disk before writing to the journal for that entry.

That is, before adding an operation to the journal, MongoDB writes all audit events on the connection that triggered the operation, up to and including the entry for the operation.

These auditing guarantees require that MongoDB run with journaling enabled.

Warning: MongoDB may lose events if the server terminates before it commits the events to the audit log. The client may receive confirmation of the event before MongoDB commits to the audit log. For example, while auditing an aggregation operation, the server might crash after returning the result but before the audit log flushes.

2.4 External Environment

These documents introduce and address concepts and strategies related to security practices in MongoDB deployments. Security and MongoDB API Interfaces (page 17) Discusses potential risks related to MongoDB’s JavaScript, HTTP and REST interfaces, including strategies to control those risks.

Security and MongoDB API Interfaces

The following section contains strategies to limit risks related to MongoDB’s available interfaces including JavaScript, HTTP, and REST interfaces.

JavaScript and the Security of the mongo Shell

The following JavaScript evaluation behaviors of the mongo shell represents risk exposures.

JavaScript Expression or JavaScript File The mongo program can evaluate JavaScript expressions using the command line --eval option. Also, the mongo program can evaluate a JavaScript file (.js) passed directly to it (e.g. mongo someFile.js).

Because the mongo program evaluates the JavaScript directly, inputs should only come from trusted sources.

.mongorc.js File If a .mongorc.js file exists, the mongo shell will evaluate a .mongorc.js file before starting. You can disable this behavior by passing the mongo --norc option.

---

29 Audit configuration can include a filter (page 80) to limit events to audit.
30 On Linux and Unix systems, mongo reads the .mongorc.js file from $HOME/.mongorc.js (i.e. ~/mongorc.js). On Windows, mongo.exe reads the .mongorc.js file from $HOME\mongorc.js or $HOMEDRIVE%$HOMEPATH%.mongorc.js.
HTTP Status Interface

**Warning:** Ensure that the HTTP status interface, the REST API, and the JSON API are all disabled in production environments to prevent potential data exposure and vulnerability to attackers.

The HTTP status interface provides a web-based interface that includes a variety of operational data, logs, and status reports regarding the mongod or mongos instance. The HTTP interface is always available on the port numbered 1000 greater than the primary mongod port. By default, the HTTP interface port is 28017, but is indirectly set using the port option which allows you to configure the primary mongod port.

Without the `net.http.RESTInterfaceEnabled` setting, this interface is entirely read-only, and limited in scope; nevertheless, this interface may represent an exposure. To disable the HTTP interface, set the `enabled` run time option or the `--nohttpinterface` command line option. See also Configuration Options (page 10).

**Note:** While MongoDB Enterprise does support Kerberos authentication, Kerberos is not supported in HTTP status interface in any version of MongoDB.

Changed in version 3.0.

Neither the HTTP status interface nor the REST API support the `SCRAM-SHA-1` challenge-response user authentication mechanism introduced in version 3.0.

REST API

The REST API to MongoDB provides additional information and write access on top of the HTTP status interface. While the REST API does not provide any support for insert, update, or remove operations, it does provide administrative access, and its accessibility represents a vulnerability in a secure environment. The REST interface is disabled by default, and is not recommended for production use.

If you must use the REST API, please control and limit access to the REST API. The REST API does not include any support for authentication, even when running with authorization enabled.

See the following documents for instructions on restricting access to the REST API interface:

- Configure Linux iptables Firewall for MongoDB (page 19)
- Configure Windows netsh Firewall for MongoDB (page 23)

3 Security Tutorials

The following tutorials provide instructions for enabling and using the security features available in MongoDB.

Network Security Tutorials (page 19) Ensure that the underlying network configuration supports a secure operating environment for MongoDB deployments, and appropriately limits access to MongoDB deployments.

Configure Linux iptables Firewall for MongoDB (page 19) Basic firewall configuration patterns and examples for `iptables` on Linux systems.

Configure Windows netsh Firewall for MongoDB (page 23) Basic firewall configuration patterns and examples for `netsh` on Windows systems.

Configure mongod and mongos for TLS/SSL (page 26) TLS/SSL allows MongoDB clients to support encrypted connections to mongod instances.

Continue reading from Network Security Tutorials (page 19) for more information on running MongoDB in secure environments.
Security Deployment Tutorials (page 36) These tutorials describe procedures for deploying MongoDB using authentication and authorization.

Authentication Tutorials (page 39) These tutorials describe procedures relevant for the configuration, operation, and maintenance of MongoDB’s access control system.

  Enable Client Access Control (page 40) Describes the process for enabling authentication for MongoDB deployments.

  Use x.509 Certificates to Authenticate Clients (page 44) Use x.509 for client authentication.

  Use x.509 Certificate for Membership Authentication (page 46) Use x.509 for internal member authentication for replica sets and sharded clusters.

  Configure MongoDB with Kerberos Authentication on Linux (page 55) For MongoDB Enterprise Linux, describes the process to enable Kerberos-based authentication for MongoDB deployments.

  Continue reading from Authentication Tutorials (page 39) for additional tutorials on configuring MongoDB’s authentication systems.

  Enable Authentication after Creating the User Administrator (page 42) Describes an alternative process for enabling authentication for MongoDB deployments.

User and Role Management Tutorials (page 66) MongoDB’s access control system provides a flexible role-based access control system that you can use to limit access to MongoDB deployments. The tutorials in this section describe the configuration and setup of the authorization system.

  Manage User and Roles (page 69) Manage users by creating new users, creating new roles, and modifying existing users.

  Continue reading from User and Role Management Tutorials (page 66) for additional tutorials on managing users and privileges in MongoDB’s authorization system.

Auditing Tutorials (page 78) MongoDB Enterprise provides auditing of operations. The tutorials in this section describe procedures to enable and configure the auditing feature.

Create a Vulnerability Report (page 83) Report a vulnerability in MongoDB.

3.1 Network Security Tutorials

The following tutorials provide information on handling network security for MongoDB.

  Configure Linux iptables Firewall for MongoDB (page 19) Basic firewall configuration patterns and examples for iptables on Linux systems.

  Configure Windows netsh Firewall for MongoDB (page 23) Basic firewall configuration patterns and examples for netsh on Windows systems.

  Configure mongod and mongos for TLS/SSL (page 26) TLS/SSL allows MongoDB clients to support encrypted connections to mongod instances.

  TLS/SSL Configuration for Clients (page 30) Configure clients to connect to MongoDB instances that use TLS/SSL.

  Upgrade a Cluster to Use TLS/SSL (page 33) Rolling upgrade process to use TLS/SSL.

Configure Linux iptables Firewall for MongoDB

On contemporary Linux systems, the iptables program provides methods for managing the Linux Kernel’s netfilter or network packet filtering capabilities. These firewall rules make it possible for administrators to
control what hosts can connect to the system, and limit risk exposure by limiting the hosts that can connect to a system.

This document outlines basic firewall configurations for **iptables** firewalls on Linux. Use these approaches as a starting point for your larger networking organization. For a detailed overview of security practices and risk management for MongoDB, see *Security Concepts* (page 5).

**See also:**

For MongoDB deployments on Amazon’s web services, see the Amazon EC2 page, which addresses Amazon’s Security Groups and other EC2-specific security features.

**Overview**

Rules in **iptables** configurations fall into chains, which describe the process for filtering and processing specific streams of traffic. Chains have an order, and packets must pass through earlier rules in a chain to reach later rules. This document addresses only the following two chains:

**INPUT** Controls all incoming traffic.

**OUTPUT** Controls all outgoing traffic.

Given the default ports (page 10) of all MongoDB processes, you must configure networking rules that permit only required communication between your application and the appropriate mongod and mongos instances.

Be aware that, by default, the default policy of **iptables** is to allow all connections and traffic unless explicitly disabled. The configuration changes outlined in this document will create rules that explicitly allow traffic from specific addresses and on specific ports, using a default policy that drops all traffic that is not explicitly allowed. When you have properly configured your **iptables** rules to allow only the traffic that you want to permit, you can Change Default Policy to DROP (page 22).

**Patterns**

This section contains a number of patterns and examples for configuring **iptables** for use with MongoDB deployments. If you have configured different ports using the **port** configuration setting, you will need to modify the rules accordingly.

**Traffic to and from mongod Instances** This pattern is applicable to all mongod instances running as standalone instances or as part of a *replica set*.

The goal of this pattern is to explicitly allow traffic to the mongod instance from the application server. In the following examples, replace `<ip-address>` with the IP address of the application server:

```
iptables -A INPUT -s <ip-address> -p tcp --destination-port 27017 -m state --state NEW,ESTABLISHED -j ACCEPT
iptables -A OUTPUT -d <ip-address> -p tcp --source-port 27017 -m state --state ESTABLISHED -j ACCEPT
```

The first rule allows all incoming traffic from `<ip-address>` on port 27017, which allows the application server to connect to the mongod instance. The second rule allows outgoing traffic from the mongod to reach the application server.

**Optional**

If you have only one application server, you can replace `<ip-address>` with either the IP address itself, such as: 198.51.100.55. You can also express this using CIDR notation as 198.51.100.55/32. If you want to permit

---

31https://docs.mongodb.org/ecosystem/platforms/amazon-ec2
a larger block of possible IP addresses you can allow traffic from a /24 using one of the following specifications for the `<ip-address>`, as follows:

10.10.10.10/24
10.10.10.10/255.255.255.0

Traffic to and from mongos Instances mongos instances provide query routing for sharded clusters. Clients connect to mongos instances, which behave from the client’s perspective as mongod instances. In turn, the mongos connects to all mongod instances that are components of the sharded cluster.

Use the same iptables command to allow traffic to and from these instances as you would from the mongod instances that are members of the replica set. Take the configuration outlined in the Traffic to and from mongod Instances (page 20) section as an example.

Traffic to and from a MongoDB Config Server Config servers, host the config database that stores metadata for sharded clusters. Each production cluster has three config servers, initiated using the mongod --configsvr option. Config servers listen for connections on port 27019. As a result, add the following iptables rules to the config server to allow incoming and outgoing connection on port 27019, for connection to the other config servers.

```
iptables -A INPUT -s <ip-address> -p tcp --destination-port 27019 -m state --state NEW,ESTABLISHED -j ACCEPT
iptables -A OUTPUT -d <ip-address> -p tcp --source-port 27019 -m state --state ESTABLISHED -j ACCEPT
```

Replace `<ip-address>` with the address or address space of all the mongod that provide config servers.

Additionally, config servers need to allow incoming connections from all of the mongos instances in the cluster and all mongod instances in the cluster. Add rules that resemble the following:

```
iptables -A INPUT -s <ip-address> -p tcp --destination-port 27019 -m state --state NEW,ESTABLISHED -j ACCEPT
```

Replace `<ip-address>` with the address of the mongos instances and the shard mongod instances.

Traffic to and from a MongoDB Shard Server For shard servers, running as mongod --shardsvr Because the default port number is 27018 when running with the shardsvr value for the clusterRole setting, you must configure the following iptables rules to allow traffic to and from each shard:

```
iptables -A INPUT -s <ip-address> -p tcp --destination-port 27018 -m state --state NEW,ESTABLISHED -j ACCEPT
iptables -A OUTPUT -d <ip-address> -p tcp --source-port 27018 -m state --state ESTABLISHED -j ACCEPT
```

Replace the `<ip-address>` specification with the IP address of all mongod. This allows you to permit incoming and outgoing traffic between all shards including constituent replica set members, to:

- all mongod instances in the shard’s replica sets.
- all mongod instances in other shards.

Furthermore, shards need to be able make outgoing connections to:

- all mongos instances.
- all mongod instances in the config servers.

Create a rule that resembles the following, and replace the `<ip-address>` with the address of the config servers and the mongos instances:

---

32 You also can run a config server by using the configsvr value for the clusterRole setting in a configuration file.
33 You can also specify the shard server option with the shardsvr value for the clusterRole setting in the configuration file. Shard members are also often conventional replica sets using the default port.
34 All shards in a cluster need to be able to communicate with all other shards to facilitate chunk and balancing operations.
iptables -A OUTPUT -d <ip-address> -p tcp --source-port 27018 --state --state ESTABLISHED -j ACCEPT

Provide Access For Monitoring Systems

1. The `mongostat` diagnostic tool, when running with the `--discover` needs to be able to reach all components of a cluster, including the config servers, the shard servers, and the `mongos` instances.

2. If your monitoring system needs access the HTTP interface, insert the following rule to the chain:

   ```
   iptables -A INPUT -s <ip-address> -p tcp --destination-port 28017 --state NEW,ESTABLISHED -j ACCEPT
   ```

   Replace `<ip-address>` with the address of the instance that needs access to the HTTP or REST interface. For all deployments, you should restrict access to this port to only the monitoring instance.

Optional

For config server `mongod` instances running with the `shardsvr` value for the `clusterRole` setting, the rule would resemble the following:

```
iptables -A INPUT -s <ip-address> -p tcp --destination-port 28018 --state --state NEW,ESTABLISHED
```

For config server `mongod` instances running with the `configsvr` value for the `clusterRole` setting, the rule would resemble the following:

```
iptables -A INPUT -s <ip-address> -p tcp --destination-port 28019 --state --state NEW,ESTABLISHED
```

Change Default Policy to DROP

The default policy for `iptables` chains is to allow all traffic. After completing all `iptables` configuration changes, you must change the default policy to DROP so that all traffic that isn’t explicitly allowed as above will not be able to reach components of the MongoDB deployment. Issue the following commands to change this policy:

```
iptables -P INPUT DROP
iptables -P OUTPUT DROP
```

Manage and Maintain `iptables` Configuration

This section contains a number of basic operations for managing and using `iptables`. There are various front end tools that automate some aspects of `iptables` configuration, but at the core all `iptables` front ends provide the same basic functionality:

Make all `iptables` Rules Persistent  By default all `iptables` rules are only stored in memory. When your system restarts, your firewall rules will revert to their defaults. When you have tested a rule set and have guaranteed that it effectively controls traffic you can use the following operations to you should make the rule set persistent.

On Red Hat Enterprise Linux, Fedora Linux, and related distributions you can issue the following command:

```
service iptables save
```

On Debian, Ubuntu, and related distributions, you can use the following command to dump the `iptables rules` to the `/etc/iptables.conf` file:
iptables-save > /etc/iptables.conf

Run the following operation to restore the network rules:
iptables-restore < /etc/iptables.conf

Place this command in your rc.local file, or in the /etc/network/if-up.d/iptables file with other similar operations.

**List all iptables Rules**  To list all of currently applied iptables rules, use the following operation at the system shell.
iptables -L

**Flush all iptables Rules**  If you make a configuration mistake when entering iptables rules or simply need to revert to the default rule set, you can use the following operation at the system shell to flush all rules:
iptables -F

If you’ve already made your iptables rules persistent, you will need to repeat the appropriate procedure in the Make all iptables Rules Persistent (page 22) section.

**Configure Windows netsh Firewall for MongoDB**

On Windows Server systems, the netsh program provides methods for managing the Windows Firewall. These firewall rules make it possible for administrators to control what hosts can connect to the system, and limit risk exposure by limiting the hosts that can connect to a system.

This document outlines basic Windows Firewall configurations. Use these approaches as a starting point for your larger networking organization. For a detailed overview of security practices and risk management for MongoDB, see Security Concepts (page 5).

**See also:**
Windows Firewall35 documentation from Microsoft.

**Overview**

*Windows Firewall* processes rules in an ordered determined by rule type, and parsed in the following order:

1. Windows Service Hardening
2. Connection security rules
3. Authenticated Bypass Rules
4. Block Rules
5. Allow Rules
6. Default Rules

By default, the policy in Windows Firewall allows all outbound connections and blocks all incoming connections.

Given the default ports (page 10) of all MongoDB processes, you must configure networking rules that permit only required communication between your application and the appropriate mongod.exe and mongos.exe instances.

The configuration changes outlined in this document will create rules which explicitly allow traffic from specific addresses and on specific ports, using a default policy that drops all traffic that is not explicitly allowed.

You can configure the Windows Firewall with using the netsh command line tool or through a windows application. On Windows Server 2008 this application is Windows Firewall With Advanced Security in Administrative Tools. On previous versions of Windows Server, access the Windows Firewall application in the System and Security control panel.

The procedures in this document use the netsh command line tool.

Patterns

This section contains a number of patterns and examples for configuring Windows Firewall for use with MongoDB deployments. If you have configured different ports using the port configuration setting, you will need to modify the rules accordingly.

Traffic to and from mongod.exe Instances  This pattern is applicable to all mongod.exe instances running as standalone instances or as part of a replica set. The goal of this pattern is to explicitly allow traffic to the mongod.exe instance from the application server.

```
netsh advfirewall firewall add rule name="Open mongod port 27017" dir=in action=allow protocol=TCP localport=27017
```

This rule allows all incoming traffic to port 27017, which allows the application server to connect to the mongod.exe instance.

Windows Firewall also allows enabling network access for an entire application rather than to a specific port, as in the following example:

```
netsh advfirewall firewall add rule name="Allowing mongod" dir=in action=allow program=" C:\mongodb\bin\mongod.exe"
```

You can allow all access for a mongos.exe server, with the following invocation:

```
netsh advfirewall firewall add rule name="Allowing mongos" dir=in action=allow program=" C:\mongodb\bin\mongos.exe"
```

Traffic to and from mongos.exe Instances  mongos.exe instances provide query routing for sharded clusters. Clients connect to mongos.exe instances, which behave from the client’s perspective as mongod.exe instances. In turn, the mongos.exe connects to all mongod.exe instances that are components of the sharded cluster.

Use the same Windows Firewall command to allow traffic to and from these instances as you would from the mongod.exe instances that are members of the replica set.

```
netsh advfirewall firewall add rule name="Open mongod shard port 27018" dir=in action=allow protocol=TCP localport=27018
```

Additionally, config servers need to allow incoming connections from all of the mongos.exe instances in the cluster and all mongod.exe instances in the cluster. Add rules that resemble the following:

```
netsh advfirewall firewall add rule name="Open mongod config svr port 27019" dir=in action=allow protocol=TCP localport=27019
```

Traffic to and from a MongoDB Config Server  Configuration servers, host the config database that stores metadata for sharded clusters. Each production cluster has three configuration servers, initiated using the mongod --configsvr option. Configuration servers listen for connections on port 27019. As a result, add the following Windows Firewall rules to the config server to allow incoming and outgoing connection on port 27019, for connection to the other config servers.

```
netsh advfirewall firewall add rule name="Open mongod config svr port 27019" dir=in action=allow protocol=TCP localport=27019
```

Additionally, config servers need to allow incoming connections from all of the mongos.exe instances in the cluster and all mongod.exe instances in the cluster. Add rules that resemble the following:

```
You also can run a config server by using the configsvr value for the clusterRole setting in a configuration file.
```
Traffic to and from a MongoDB Shard Server  For shard servers, running as mongod --shardsvr. Because the default port number is 27018 when running with the shardsvr value for the clusterRole setting, you must configure the following Windows Firewall rules to allow traffic to and from each shard:

- netsh advfirewall firewall add rule name="Open mongod shardsvr inbound" dir=in action=allow protocol=TCP remoteip=<ip-address> localport=27018
- netsh advfirewall firewall add rule name="Open mongod shardsvr outbound" dir=out action=allow protocol=TCP remoteip=<ip-address> localport=27018

Replace the <ip-address> specification with the IP address of all mongod.exe instances. This allows you to permit incoming and outgoing traffic between all shards including constituent replica set members to:

- all mongod.exe instances in the shard’s replica sets.
- all mongod.exe instances in other shards.

Furthermore, shards need to be able make outgoing connections to:

- all mongos.exe instances.
- all mongod.exe instances in the config servers.

Create a rule that resembles the following, and replace the <ip-address> with the address of the config servers and the mongos.exe instances:

- netsh advfirewall firewall add rule name="Open mongod config svr outbound" dir=out action=allow protocol=TCP remoteip=<ip-address> localport=27018

Provide Access For Monitoring Systems

1. The mongostat diagnostic tool, when running with the --discover needs to be able to reach all components of a cluster, including the config servers, the shard servers, and the mongos.exe instances.

2. If your monitoring system needs access the HTTP interface, insert the following rule to the chain:

   - netsh advfirewall firewall add rule name="Open mongod HTTP monitoring inbound" dir=in action=allow protocol=TCP remoteip=<ip-address> localport=28017

Replace <ip-address> with the address of the instance that needs access to the HTTP or REST interface. For all deployments, you should restrict access to this port to only the monitoring instance.

Optional

For config server mongod instances running with the shardsvr value for the clusterRole setting, the rule would resemble the following:

- netsh advfirewall firewall add rule name="Open mongos HTTP monitoring inbound" dir=in action=allow protocol=TCP remoteip=<ip-address> localport=28018

For config server mongod instances running with the configsvr value for the clusterRole setting, the rule would resemble the following:

- netsh advfirewall firewall add rule name="Open mongod configsvr HTTP monitoring inbound" dir=in action=allow protocol=TCP remoteip=<ip-address> localport=28019

---

37 You can also specify the shard server option with the shardsvr value for the clusterRole setting in the configuration file. Shard members are also often conventional replica sets using the default port.

38 All shards in a cluster need to be able to communicate with all other shards to facilitate chunk and balancing operations.
Manage and Maintain Windows Firewall Configurations

This section contains a number of basic operations for managing and using `netsh`. While you can use the GUI front ends to manage the Windows Firewall, all core functionality is accessible from `netsh`.

Delete all Windows Firewall Rules  To delete the firewall rule allowing `mongod.exe` traffic:

```
netsh advfirewall firewall delete rule name="Open mongod port 27017" protocol=tcp localport=27017
```

```
netsh advfirewall firewall delete rule name="Open mongod shard port 27018" protocol=tcp localport=27018
```

List All Windows Firewall Rules  To return a list of all Windows Firewall rules:

```
netsh advfirewall firewall show rule name=all
```

Reset Windows Firewall  To reset the Windows Firewall rules:

```
netsh advfirewall reset
```

Backup and Restore Windows Firewall Rules  To simplify administration of larger collection of systems, you can export or import firewall systems from different servers) rules very easily on Windows:

Export all firewall rules with the following command:

```
netsh advfirewall export "C:\temp\MongoDBfw.wfw"
```

Replace "C:\temp\MongoDBfw.wfw" with a path of your choosing. You can use a command in the following form to import a file created using this operation:

```
netsh advfirewall import "C:\temp\MongoDBfw.wfw"
```

Configure mongod and mongos for TLS/SSL

Overview

This document helps you to configure MongoDB to support TLS/SSL. MongoDB clients can use TLS/SSL to encrypt connections to `mongod` and `mongos` instances. MongoDB TLS/SSL implementation uses OpenSSL libraries.

Note: Although TLS is the successor to SSL, this page uses the more familiar term SSL to refer to TLS/SSL.

These instructions assume that you have already installed a build of MongoDB that includes SSL support and that your client driver supports SSL. For instructions on upgrading a cluster currently not using SSL to using SSL, see Upgrade a Cluster to Use TLS/SSL (page 33).

Changed in version 2.6: MongoDB’s SSL encryption only allows use of strong SSL ciphers with a minimum of 128-bit key length for all connections.

Prerequisites

Important: A full description of TLS/SSL, PKI (Public Key Infrastructure) certificates, and Certificate Authority
is beyond the scope of this document. This page assumes prior knowledge of TLS/SSL as well as access to valid certificates.

**MongoDB Support**  New in version 3.0: Most MongoDB distributions now include support for SSL. Certain distributions of MongoDB do not contain support for SSL. To use SSL, be sure to choose a package that supports SSL. All MongoDB Enterprise supported platforms include SSL support.

**Client Support**  See *TLS/SSL Configuration for Clients* (page 30) to learn about SSL support for Python, Java, Ruby, and other clients.

**Certificate Authorities**  For production use, your MongoDB deployment should use valid certificates generated and signed by a single certificate authority. You or your organization can generate and maintain an independent certificate authority, or use certificates generated by a third-party SSL vendor. Obtaining and managing certificates is beyond the scope of this documentation.

**.pem File**  Before you can use SSL, you must have a .pem file containing a public key certificate and its associated private key.

MongoDB can use any valid SSL certificate issued by a certificate authority, or a self-signed certificate. If you use a self-signed certificate, although the communications channel will be encrypted, there will be no validation of server identity. Although such a situation will prevent eavesdropping on the connection, it leaves you vulnerable to a man-in-the-middle attack. Using a certificate signed by a trusted certificate authority will permit MongoDB drivers to verify the server’s identity.

In general, avoid using self-signed certificates unless the network is trusted.

Additionally, with regards to *authentication among replica set/sharded cluster members* (page 8), in order to minimize exposure of the private key and allow hostname validation, it is advisable to use different certificates on different servers.

For testing purposes, you can generate a self-signed certificate and private key on a Unix system with a command that resembles the following:

```
cd /etc/ssl/
openssl req -newkey rsa:2048 -new -x509 -days 365 -nodes -out mongodb-cert.crt -keyout mongodb-cert.key
```

This operation generates a new, self-signed certificate with no passphrase that is valid for 365 days. Once you have the certificate, concatenate the certificate and private key to a .pem file, as in the following example:

```
cat mongodb-cert.key mongodb-cert.crt > mongodb.pem
```

See also:

*Use x.509 Certificates to Authenticate Clients* (page 44)

**Procedures**

**Set Up mongod and mongos with SSL Certificate and Key**  To use SSL in your MongoDB deployment, include the following run-time options with mongod and mongos:

• **net.ssl.mode** set to **requireSSL**. This setting restricts each server to use only SSL encrypted connections. You can also specify either the value **allowSSL** or **preferSSL** to set up the use of mixed SSL modes on a port. See **net.ssl.mode** for details.

• **PEMKeyfile** with the **.pem** file that contains the SSL certificate and key.

Consider the following syntax for **mongod**:

```
mongod --sslMode requireSSL --sslPEMKeyFile <pem>
```

For example, given an SSL certificate located at `/etc/ssl/mongodb.pem`, configure **mongod** to use SSL encryption for all connections with the following command:

```
mongod --sslMode requireSSL --sslPEMKeyFile /etc/ssl/mongodb.pem
```

**Note:**

• Specify `<pem>` with the full path name to the certificate.

• If the private key portion of the `<pem>` is encrypted, specify the passphrase. See **SSL Certificate Passphrase** (page 30).

You may also specify these options in the **configuration file**, as in the following examples:

If using the **YAML configuration file format**:

```
net:
  ssl:
    mode: requireSSL
    PEMKeyFile: /etc/ssl/mongodb.pem
```

Or, if using the older **older configuration file format**:

```
sslMode = requireSSL
sslPEMKeyFile = /etc/ssl/mongodb.pem
```

To connect to **mongod** and **mongos** instances using SSL, the **mongo** shell and MongoDB tools must include the **--ssl** option. See **TLS/SSL Configuration for Clients** (page 30) for more information on connecting to **mongod** and **mongos** running with SSL.

**See also:**

*Upgrade a Cluster to Use TLS/SSL* (page 33)

**Set Up mongod and mongos with Certificate Validation** To set up **mongod** or **mongos** for SSL encryption using an SSL certificate signed by a certificate authority, include the following run-time options during startup:

• **net.ssl.mode** set to **requireSSL**. This setting restricts each server to use only SSL encrypted connections. You can also specify either the value **allowSSL** or **preferSSL** to set up the use of mixed SSL modes on a port. See **net.ssl.mode** for details.

• **PEMKeyfile** with the name of the **.pem** file that contains the signed SSL certificate and key.

• **CAFile** with the name of the **.pem** file that contains the root certificate chain from the Certificate Authority.

Consider the following syntax for **mongod**:

```
mongod --sslMode requireSSL --sslPEMKeyFile <pem> --sslCAFile <ca>
```

---

41 [http://docs.mongodb.org/v2.4/reference/configuration-options](http://docs.mongodb.org/v2.4/reference/configuration-options)
For example, given a signed SSL certificate located at `/etc/ssl/mongodb.pem` and the certificate authority file at `/etc/ssl/ca.pem`, you can configure `mongod` for SSL encryption as follows:

```
mongod --sslMode requireSSL --sslPEMKeyFile /etc/ssl/mongodb.pem --sslCAFile /etc/ssl/ca.pem
```

**Note:**
- Specify the `<pem>` file and the `<ca>` file with either the full path name or the relative path name.
- If the `<pem>` is encrypted, specify the passphrase. See *SSL Certificate Passphrase* (page 30).

You may also specify these options in the configuration file, as in the following examples:

If using the YAML configuration file format:

```yaml
net:
  ssl:
    mode: requireSSL
    PEMKeyFile: /etc/ssl/mongodb.pem
    CAFile: /etc/ssl/ca.pem
```

Or, if using the older older configuration file format:

```plaintext
sslMode = requireSSL
sslPEMKeyFile = /etc/ssl/mongodb.pem
sslCAFile = /etc/ssl/ca.pem
```

To connect to `mongod` and `mongos` instances using SSL, the `mongo` tools must include the both the `--ssl` and `--sslPEMKeyFile` option. See *TLS/SSL Configuration for Clients* (page 30) for more information on connecting to `mongod` and `mongos` running with SSL.

**See also:**

*Upgrade a Cluster to Use TLS/SSL* (page 33)

**Block Revoked Certificates for Clients** To prevent clients with revoked certificates from connecting, include the `sslCRLFile` to specify a `.pem` file that contains revoked certificates.

For example, the following `mongod` with SSL configuration includes the `sslCRLFile` setting:

```
mongod --sslMode requireSSL --sslCRLFile /etc/ssl/ca-crl.pem --sslPEMKeyFile /etc/ssl/mongodb.pem --sslCAFile /etc/ssl/ca.pem
```

Clients with revoked certificates in the `/etc/ssl/ca-crl.pem` will not be able to connect to this `mongod` instance.

**Validate Only if a Client Presents a Certificate** In most cases it is important to ensure that clients present valid certificates. However, if you have clients that cannot present a client certificate, or are transitioning to using a certificate authority you may only want to validate certificates from clients that present a certificate.

If you want to bypass validation for clients that don’t present certificates, include the `allowConnectionsWithoutCertificates` run-time option with `mongod` and `mongos`. If the client does not present a certificate, no validation occurs. These connections, though not validated, are still encrypted using SSL.

For example, consider the following `mongod` with an SSL configuration that includes the `allowConnectionsWithoutCertificates` setting:

```
mongod --sslMode requireSSL --sslPEMKeyFile /etc/ssl/mongodb.pem --sslCAFile /etc/ssl/ca.pem --allowConnectionsWithoutCertificates
```

42 [http://docs.mongodb.org/v2.4.0/reference/configuration-options](http://docs.mongodb.org/v2.4.0/reference/configuration-options)
Then, clients can connect either with the option `--ssl` and no certificate or with the option `--ssl` and a valid certificate. See **TLS/SSL Configuration for Clients** (page 30) for more information on SSL connections for clients.

Note: If the client presents a certificate, the certificate must be a valid certificate.

All connections, including those that have not presented certificates are encrypted using SSL.

### SSL Certificate Passphrase

The PEM files for `PEMKeyfile` and `ClusterFile` may be encrypted. With encrypted PEM files, you must specify the passphrase at startup with a command-line or a configuration file option or enter the passphrase when prompted.

Changed in version 2.6: In previous versions, you can only specify the passphrase with a command-line or a configuration file option.

To specify the passphrase in clear text on the command line or in a configuration file, use the `PEMKeyPassword` and/or the `ClusterPassword` option.

To have MongoDB prompt for the passphrase at the start of `mongod` or `mongos` and avoid specifying the passphrase in clear text, omit the `PEMKeyPassword` and/or the `ClusterPassword` option. MongoDB will prompt for each passphrase as necessary.

Important: The passphrase prompt option is available if you run the MongoDB instance in the foreground with a connected terminal. If you run `mongod` or `mongos` in a non-interactive session (e.g. without a terminal or as a service on Windows), you cannot use the passphrase prompt option.

### Run in FIPS Mode

Note: FIPS-compatible SSL is available only in MongoDB Enterprise. See **Configure MongoDB for FIPS** (page 34) for more information.

See **Configure MongoDB for FIPS** (page 34) for more details.

### TLS/SSL Configuration for Clients

Clients must have support for TLS/SSL to work with a `mongod` or a `mongos` instance that has TLS/SSL support enabled.

Important: A full description of TLS/SSL, PKI (Public Key Infrastructure) certificates, and Certificate Authority is beyond the scope of this document. This page assumes prior knowledge of TLS/SSL as well as access to valid certificates.

Note: Although TLS is the successor to SSL, this page uses the more familiar term SSL to refer to TLS/SSL.

See also:

*Configure mongod and mongos for TLS/SSL* (page 26).

---

mongo Shell SSL Configuration

For SSL connections, you must use the mongo shell built with SSL support or distributed with MongoDB Enterprise.

New in version 3.0: Most MongoDB distributions now include support for SSL.

The mongo shell provides various mongo-shell-ssl settings, including:

- `--ssl`
- `--sslPEMKeyFile` with the name of the .pem file that contains the SSL certificate and key.
- `--sslCAFile` with the name of the .pem file that contains the certificate from the Certificate Authority (CA).

Changed in version 3.0: When running mongo with the `--ssl` option, you must include either `--sslCAFile` or `--sslAllowInvalidCertificates`.

This restriction does not apply to the MongoDB tools. However, running the tools without `--sslCAFile` creates the same vulnerability to invalid certificates.

**Warning:** For SSL connections (`--ssl`) to mongod and mongos, if the mongo shell (or MongoDB tools (page 33)) runs without the `--sslCAFile <CAFile>` option (i.e. specifies the `--sslAllowInvalidCertificates` instead), the mongo shell (or MongoDB tools (page 33)) will not attempt to validate the server certificates. This creates a vulnerability to expired mongod and mongos certificates as well as to foreign processes posing as valid mongod or mongos instances. Ensure that you **always** specify the CA file to validate the server certificates in cases where intrusion is a possibility.

- `--sslPEMKeyPassword` option if the client certificate-key file is encrypted.

For a complete list of the mongo shell’s SSL settings, see *mongo-shell-ssl*.

**Connect to MongoDB Instance with SSL Encryption**  To connect to a mongod or mongos instance that requires only a SSL encryption mode (page 27), start mongo shell with `--ssl` and include the `--sslCAFile` to validate the server certificates.

```
mongo --ssl --sslCAFile /etc/ssl/ca.pem
```

Changed in version 3.0: When running mongo with the `--ssl` option, you must include either `--sslCAFile` or `--sslAllowInvalidCertificates`.

This restriction does not apply to the MongoDB tools. However, running the tools without `--sslCAFile` creates the same vulnerability to invalid certificates.

**Connect to MongoDB Instance that Requires Client Certificates**  To connect to a mongod or mongos that requires CA-signed client certificates (page 28), start the mongo shell with `--ssl`, the `--sslPEMKeyFile` option to specify the signed certificate-key file, and the `--sslCAFile` to validate the server certificates.

```
mongo --ssl --sslPEMKeyFile /etc/ssl/client.pem --sslCAFile /etc/ssl/ca.pem
```

Changed in version 3.0: When running mongo with the `--ssl` option, you must include either `--sslCAFile` or `--sslAllowInvalidCertificates`.

This restriction does not apply to the MongoDB tools. However, running the tools without `--sslCAFile` creates the same vulnerability to invalid certificates.
Connect to MongoDB Instance that Validates when Presented with a Certificate

To connect to a mongod or mongos instance that only requires valid certificates when the client presents a certificate, start mongo shell either:

- with the --ssl, --sslCAFile, and no certificate or
- with the --ssl, --sslCAFile, and a valid signed certificate.

Changed in version 3.0: When running mongo with the --ssl option, you must include either --sslCAFile or --sslAllowInvalidCertificates.

This restriction does not apply to the MongoDB tools. However, running the tools without --sslCAFile creates the same vulnerability to invalid certificates.

For example, if mongod is running with weak certificate validation, both of the following mongo shell clients can connect to that mongod:

```bash
mongo --ssl --sslCAFile /etc/ssl/ca.pem
mongo --ssl --sslPEMKeyFile /etc/ssl/client.pem --sslCAFile /etc/ssl/ca.pem
```

**Important:** If the client presents a certificate, the certificate must be valid.

MongoDB Cloud Manager and Ops Manager Monitoring Agent

The MongoDB Cloud Manager Monitoring agent will also have to connect via SSL in order to gather its statistics. Because the agent already utilizes SSL for its communications to the MongoDB Cloud Manager servers, this is just a matter of enabling SSL support in MongoDB Cloud Manager itself on a per host basis. See the MongoDB Cloud Manager documentation\(^{44}\) for more information about SSL configuration.

For Ops Manager, see Ops Manager documentation\(^{45}\).

**MongoDB Drivers**

The MongoDB Drivers support for connection to SSL enabled MongoDB. See:

- C Driver\(^{46}\)
- C++ Driver\(^{47}\)
- C# Driver\(^{48}\)
- Java Driver\(^{49}\)
- Node.js Driver\(^{50}\)
- Perl Driver\(^{51}\)
- PHP Driver\(^{52}\)
- Python Driver\(^{53}\)

• Ruby Driver
• Scala Driver

MongoDB Tools

Changed in version 2.6.

Various MongoDB utility programs support SSL. These tools include:

- mongodump
- mongoexport
- mongofiles
- mongoimport
- mongooplog
- mongorestore
- mongostat
- mongotop

To use SSL connections with these tools, use the same SSL options as the mongo shell. See *mongo Shell SSL Configuration* (page 31).

Upgrade a Cluster to Use TLS/SSL

Changed in version 3.0: Most MongoDB distributions now include support for TLS/SSL. See *Configure mongod and mongos for TLS/SSL* (page 26) and *TLS/SSL Configuration for Clients* (page 30) for more information about TLS/SSL and MongoDB.

**Important:** A full description of TLS/SSL, PKI (Public Key Infrastructure) certificates, and Certificate Authority is beyond the scope of this document. This page assumes prior knowledge of TLS/SSL as well as access to valid certificates.

Changed in version 2.6.

The MongoDB server supports listening for both TLS/SSL encrypted and unencrypted connections on the same TCP port. This allows upgrades of MongoDB clusters to use TLS/SSL encrypted connections.

To upgrade from a MongoDB cluster using no TLS/SSL encryption to one using *only* TLS/SSL encryption, use the following rolling upgrade process:

1. For each node of a cluster, start the node with the option *--sslMode* set to *allowSSL*. The *--sslMode allowSSL* setting allows the node to accept both TLS/SSL and non-TLS/non-SSL incoming connections. Its connections to other servers do not use TLS/SSL. Include other TLS/SSL options (page 26) as well as any other options that are required for your specific configuration. For example:

   mongod --replSet <name> --sslMode allowSSL --sslPEMKeyFile <path to TLS/SSL Certificate and key PEM file>
   mongod --replSet <name> --sslMode allowSSL --sslPEMKeyFile <path to TLS/SSL Certificate and key PEM file>

Upgrade all nodes of the cluster to these settings.

You may also specify these options in the configuration file. If using a YAML format configuration file, specify the following settings in the file:

---

54 [http://docs.mongodb.org/ecosystem/tutorial/ruby-driver-tutorial/#mongodb-x509-mechanism](http://docs.mongodb.org/ecosystem/tutorial/ruby-driver-tutorial/#mongodb-x509-mechanism)
net:
  ssl:
    mode: <disabled|allowSSL|preferSSL|requireSSL>
    PEMKeyFile: <path to TLS/SSL certificate and key PEM file>
    CAFile: <path to root CA PEM file>

Or, if using the older configuration file format:\(^{56}\):

    sslMode = <disabled|allowSSL|preferSSL|requireSSL>
    sslPEMKeyFile = <path to TLS/SSL certificate and key PEM file>
    sslCAFile = <path to root CA PEM file>

2. Switch all clients to use TLS/SSL. See TLS/SSL Configuration for Clients (page 30).

3. For each node of a cluster, use the setParameter command to update the sslMode to preferSSL.\(^{57}\)
   With preferSSL as its net.ssl.mode, the node accepts both TLS/SSL and non-TLS/non-SSL incoming
   connections, and its connections to other servers use TLS/SSL. For example:

   db.getSiblingDB('admin').runCommand( { setParameter: 1, sslMode: "preferSSL" } )

   Upgrade all nodes of the cluster to these settings.
   At this point, all connections should be using TLS/SSL.

4. For each node of the cluster, use the setParameter command to update the sslMode to requireSSL.\(^{58}\)
   With requireSSL as its net.ssl.mode, the node will reject any non-TLS/non-SSL connections. For
   example:

   db.getSiblingDB('admin').runCommand( { setParameter: 1, sslMode: "requireSSL" } )

5. After the upgrade of all nodes, edit the configuration file with the appropriate TLS/SSL settings to
   ensure that upon subsequent restarts, the cluster uses TLS/SSL.

Configure MongoDB for FIPS

New in version 2.6.

Overview

The Federal Information Processing Standard (FIPS) is a U.S. government computer security standard used to certify
software modules and libraries that encrypt and decrypt data securely. You can configure MongoDB to run with a
FIPS 140-2 certified library for OpenSSL. Configure FIPS to run by default or as needed from the command line.

Prerequisites

**Important:** A full description of FIPS and TLS/SSL is beyond the scope of this document. This tutorial assumes
prior knowledge of FIPS and TLS/SSL.

Only the MongoDB Enterprise\(^{58}\) version supports FIPS mode. See [http://docs.mongodb.org/manual/administration/install-enterprise](http://docs.mongodb.org/manual/administration/install-enterprise) to download and install MongoDB Enterprise\(^{59}\) to use FIPS mode.

---

\(^{56}\) [http://docs.mongodb.org/v2.4/reference/configuration-options](http://docs.mongodb.org/v2.4/reference/configuration-options)

\(^{57}\) As an alternative to using the setParameter command, you can also restart the nodes with the appropriate TLS/SSL options and values.

Your system must have an OpenSSL library configured with the FIPS 140-2 module. At the command line, type `openssl version` to confirm your OpenSSL software includes FIPS support.

For Red Hat Enterprise Linux 6.x (RHEL 6.x) or its derivatives such as CentOS 6.x, the OpenSSL toolkit must be at least `openssl-1.0.1e-16.el6_5` to use FIPS mode. To upgrade the toolkit for these platforms, issue the following command:

```
sudo yum update openssl
```

Some versions of Linux periodically execute a process to `prelink` dynamic libraries with pre-assigned addresses. This process modifies the OpenSSL libraries, specifically `libcrypto`. The OpenSSL FIPS mode will subsequently fail the signature check performed upon startup to ensure `libcrypto` has not been modified since compilation.

To configure the Linux prelink process to not prelink `libcrypto`:

```
sudo bash -c "echo '-b /usr/lib64/libcrypto.so.*' >>/etc/prelink.conf.d/openssl-prelink.conf"
```

**Considerations**

FIPS is property of the encryption system and not the access control system. However, if your environment requires FIPS compliant encryption and access control, you must ensure that the access control system uses only FIPS-compliant encryption.

MongoDB’s FIPS support covers the way that MongoDB uses OpenSSL for network encryption and X509 authentication. If you use Kerberos or LDAP Proxy authentication, you must ensure that these external mechanisms are FIPS-compliant. MONGODB-CR authentication is not FIPS compliant.

**Procedure**

**Configure MongoDB to use TLS/SSL.** See *Configure mongod and mongos for TLS/SSL* (page 26) for details about configuring OpenSSL.

**Run mongod or mongos instance in FIPS mode** Perform these steps after you *Configure mongod and mongos for TLS/SSL* (page 26).

**Step 1: Change configuration file.** To configure your mongod or mongos instance to use FIPS mode, shut down the instance and update the configuration file with the following setting:

```
net:
  ssl:
    FIPSMode: true
```

**Step 2: Start mongod or mongos instance with configuration file.** For example, run this command to start the mongod instance with its configuration file:

```
mongod --config /etc/mongod.conf
```

**Confirm FIPS mode is running** Check the server log file for a message FIPS is active:

```
FIPS 140-2 mode activated
```
3.2 Security Deployment Tutorials

The following tutorials provide information in deploying MongoDB using authentication and authorization.

**Deploy Replica Set and Configure Authentication and Authorization (page 36)** Configure a replica set that has authentication enabled.

**Deploy Replica Set and Configure Authentication and Authorization**

**Overview**

With authentication (page 6) enabled, MongoDB forces all clients to identify themselves before granting access to the server. Authorization (page 14), in turn, allows administrators to define and limit the resources and operations that a user can access. Using authentication and authorization is a key part of a complete security strategy.

All MongoDB deployments support authentication. By default, MongoDB does not require authorization checking. You can enforce authorization checking when deploying MongoDB, or on an existing deployment; however, you cannot enable authorization checking on a running deployment without downtime.

This tutorial provides a procedure for creating a MongoDB replica set that uses the challenge-response authentication mechanism. The tutorial includes creation of a minimal authorization system to support basic operations.

**Considerations**

**Authentication** In this procedure, you will configure MongoDB using the default challenge-response authentication mechanism, using the keyFile to supply the password for inter-process authentication (page 8). The content of the key file is the shared secret used for all internal authentication.

All deployments that enforce authorization checking should have one user administrator user that can create new users and modify existing users. During this procedure you will create a user administrator that you will use to administer this deployment.

**Architecture** In a production, deploy each member of the replica set to its own machine and if possible bind to the standard MongoDB port of 27017. Use the bind_ip option to ensure that MongoDB listens for connections from applications on configured addresses.

For a geographically distributed replica sets, ensure that the majority of the set’s mongod instances reside in the primary site.

See [http://docs.mongodb.org/manual/core/replica-set-architectures](http://docs.mongodb.org/manual/core/replica-set-architectures) for more information.

**Connectivity** Ensure that network traffic can pass between all members of the set and all clients in the network securely and efficiently. Consider the following:

- Establish a virtual private network. Ensure that your network topology routes all traffic between members within a single site over the local area network.
- Configure access control to prevent connections from unknown clients to the replica set.
- Configure networking and firewall rules so that incoming and outgoing packets are permitted only on the default MongoDB port and only from within your deployment.

Finally ensure that each member of a replica set is accessible by way of resolvable DNS or hostnames. You should either configure your DNS names appropriately or set up your systems’ /etc/hosts file to reflect this configuration.
Configuration  Specify the run time configuration on each system in a configuration file stored in 
/etc/mongod.conf or a related location. Create the directory where MongoDB stores data files before deploying 
MongoDB.

For more information about the run time options used above and other configuration options, see 

Procedure

This procedure deploys a replica set in which all members use the same key file.

Step 1: Start one member of the replica set.  This mongod should not enable auth.

Step 2: Create administrative users. The following operations will create two users: a user administrator that will 
be able to create and modify users (siteUserAdmin), and a root (page 93) user (siteRootAdmin) that you 
will use to complete the remainder of the tutorial:

```
use admin
db.createUser( {
    user: "siteUserAdmin",
    pwd: "<password>",
    roles: [ { role: "userAdminAnyDatabase", db: "admin" } ]
 });
db.createUser( {
    user: "siteRootAdmin",
    pwd: "<password>",
    roles: [ { role: "root", db: "admin" } ]
 });
```

Step 3: Stop the mongod instance.

Step 4: Create the key file to be used by each member of the replica set.  Create the key file your deployment will 
use to authenticate servers to each other.

To generate pseudo-random data to use for a keyfile, issue the following openssl command:

```
openssl rand -base64 741 > mongodb-keyfile
chmod 600 mongodb-keyfile
```

You may generate a key file using any method you choose. Always ensure that the password stored in the key file is 
both long and contains a high amount of entropy. Using openssl in this manner helps generate such a key.

Step 5: Copy the key file to each member of the replica set.  Copy the mongodb-keyfile to all hosts where 
components of a MongoDB deployment run. Set the permissions of these files to 600 so that only the owner of the 
file can read or write this file to prevent other users on the system from accessing the shared secret.

Step 6: Start each member of the replica set with the appropriate options.  For each member, start a mongod 
and specify the key file and the name of the replica set. Also specify other parameters as needed for your deployment. 
For replication-specific parameters, see cli-mongod-replica-set required by your deployment.

If your application connects to more than one replica set, each set should have a distinct name. Some drivers group 
replica set connections by replica set name.
The following example specifies parameters through the --keyFile and --replSet command-line options:

```
mongod --keyFile /mysecretdirectory/mongodb-keyfile --replSet "rs0"
```

The following example specifies parameters through a configuration file:

```
mongod --config $HOME/.mongodb/config
```

In production deployments, you can configure a control script to manage this process. Control scripts are beyond the scope of this document.

**Step 7: Connect to the member of the replica set where you created the administrative users.** Connect to the replica set member you started and authenticate as the siteRootAdmin user. From the mongo shell, use the following operation to authenticate:

```
use admin
db.auth("siteRootAdmin", "<password>"o);
```

**Step 8: Initiate the replica set.** Use rs.initiate() on the replica set member:

```
rs.initiate()
```

MongoDB initiates a set that consists of the current member and that uses the default replica set configuration.

**Step 9: Verify the initial replica set configuration.** Use rs.conf() to display the replica set configuration object:

```
rs.conf()
```

The replica set configuration object resembles the following:

```
{
   "_id" : "rs0",
   "version" : 1,
   "members" : [
      {
         "_id" : 1,
         "host" : "mongodb0.example.net:27017"
      }
   ]
}
```

**Step 10: Add the remaining members to the replica set.** Add the remaining members with the rs.add() method.

The following example adds two members:

```
rs.add("mongodb1.example.net")
rs.add("mongodb2.example.net")
```

When complete, you have a fully functional replica set. The new replica set will elect a primary.

**Step 11: Check the status of the replica set.** Use the rs.status() operation:
Step 12: Create additional users to address operational requirements. You can use built-in roles (page 85) to create common types of database users, such as the dbOwner (page 87) role to create a database administrator, the readWrite (page 86) role to create a user who can update data, or the read (page 85) role to create a user who can search data but no more. You also can define custom roles (page 15).

For example, the following creates a database administrator for the products database:

```javascript
use products
db.createUser(
{
    user: "productsDBAdmin",
pwd: "password",
roles:
[
    {
        role: "dbOwner",
        db: "products"
    }
]
}
)
```

For an overview of roles and privileges, see Authorization (page 14). For more information on adding users, see Manage User and Roles (page 69).

### 3.3 Authentication Tutorials

The following tutorials provide instructions for MongoDB’s authentication related features.

*Enable Client Access Control* (page 40) Describes the process for enabling authentication for MongoDB deployments.

*Enable Authentication in a Sharded Cluster* (page 41) Control access to a sharded cluster through a key file and the keyFile setting on each of the cluster’s components.

*Enable Authentication after Creating the User Administrator* (page 42) Describes an alternative process for enabling authentication for MongoDB deployments.

*Use x.509 Certificates to Authenticate Clients* (page 44) Use x.509 for client authentication.

*Use x.509 Certificate for Membership Authentication* (page 46) Use x.509 for internal member authentication for replica sets and sharded clusters.

*Authenticate Using SASL and LDAP with ActiveDirectory* (page 49) Describes the process for authentication using SASL/LDAP with ActiveDirectory.

*Authenticate Using SASL and LDAP with OpenLDAP* (page 52) Describes the process for authentication using SASL/LDAP with OpenLDAP.

*Configure MongoDB with Kerberos Authentication on Linux* (page 55) For MongoDB Enterprise Linux, describes the process to enable Kerberos-based authentication for MongoDB deployments.

*Configure MongoDB with Kerberos Authentication on Windows* (page 59) For MongoDB Enterprise for Windows, describes the process to enable Kerberos-based authentication for MongoDB deployments.

*Authenticate to a MongoDB Instance or Cluster* (page 61) Describes the process for authenticating to MongoDB systems using the mongo shell.
**Enable Client Access Control**

**Overview**

Enabling access control on a MongoDB instance restricts access to the instance by requiring that users identify themselves when connecting. In this procedure, you enable access control and then create the instance’s first user, which must be a user administrator. The user administrator grants further access to the instance by creating additional users.

**Considerations**

If you create the user administrator before enabling access control, MongoDB disables the *localhost exception* (page 9). In that case, you must use the “*Enable Authentication after Creating the User Administrator*” (page 42) procedure to enable access control.

This procedure uses the *localhost exception* (page 9) to allow you to create the first user after enabling authentication. See *Localhost Exception* (page 9) and *Authentication* (page 6) for more information.

**Procedure**

**Step 1: Start the MongoDB instance with authentication enabled.** Start the mongod or mongos instance with the authorization or keyFile setting. Use authorization on a standalone instance. Use keyFile on an instance in a replica set or sharded cluster.

For example, to start a mongod with authentication enabled and a key file stored in /private/var, first set the following option in the mongod’s configuration file:

```plaintext
security:
  keyFile: /private/var/key.pem
```

Then start the mongod and specify the config file. For example:

```
mongod --config /etc/mongodb/mongodb.conf
```

After you enable authentication, only the user administrator can connect to the MongoDB instance. The user administrator must log in and grant further access to the instance by creating additional users.

**Step 2: Connect to the MongoDB instance via the localhost exception.** Connect to the MongoDB instance from a client running on the same system. This access is made possible by the *localhost exception* (page 9).

**Step 3: Create the system user administrator.** Add the user with the *userAdminAnyDatabase* (page 92) role, and only that role.

The following example creates the user siteUserAdmin user on the admin database:
use admin
db.createUser(
    {
        user: "siteUserAdmin",
        pwd: "password",
        roles: [ { role: "userAdminAnyDatabase", db: "admin" } ]
    }
)

After you create the user administrator, the localhost exception (page 9) is no longer available.

The mongo shell executes a number of commands at start up. As a result, when you log in as the user administrator, you may see authentication errors from one or more commands. You may ignore these errors, which are expected, because the userAdminAnyDatabase (page 92) role does not have permissions to run some of the start up commands.

**Step 4: Create additional users.** Login in with the user administrator’s credentials and create additional users. See Manage User and Roles (page 69).

**Next Steps**

If you need to disable access control for any reason, restart the process without the authorization or keyFile setting.

**Enable Authentication in a Sharded Cluster**

New in version 2.0: Support for authentication with sharded clusters.

**Overview**

When authentication is enabled on a sharded cluster, every client that accesses the cluster must provide credentials. This includes MongoDB instances that access each other within the cluster.

To enable authentication on a sharded cluster, you must enable authentication individually on each component of the cluster. This means enabling authentication on each mongos and each mongod, including each config server, and all members of a shard’s replica set.

Authentication requires an authentication mechanism and, in most cases, a keyfile. The content of the key file must be the same on all cluster members.

**Considerations**

It is not possible to convert an existing sharded cluster that does not enforce access control to require authentication without taking all components of the cluster offline for a short period of time.

As described in Localhost Exception (page 9), the localhost exception will apply to the individual shards unless you either create an administrative user or disable the localhost exception on each shard.
**Procedure**

**Step 1: Create a key file.** Create the key file your deployment will use to authenticate servers to each other. To generate pseudo-random data to use for a keyfile, issue the following `openssl` command:

```bash
openssl rand -base64 741 > mongodb-keyfile
chmod 600 mongodb-keyfile
```

You may generate a key file using any method you choose. Always ensure that the password stored in the key file is both long and contains a high amount of entropy. Using `openssl` in this manner helps generate such a key.

**Step 2: Enable authentication on each component in the cluster.** On each `mongos` and `mongod` in the cluster, including all config servers and shards, specify the key file using one of the following approaches:

**Specify the key file in the configuration file.** In the configuration file, set the `keyFile` option to the key file’s path and then start the component, as in the following example:

```plaintext
security:
  keyFile: /srv/mongodb/keyfile
```

**Specify the key file at runtime.** When starting the component, set the `--keyFile` option, which is an option for both `mongos` instances and `mongod` instances. Set the `--keyFile` to the key file’s path. The `keyFile` setting implies the `authorization` setting, which means in most cases you do not need to set `authorization` explicitly.

**Step 3: Add users.** While connected to a `mongos`, add the first administrative user and then add subsequent users. See *Create a User Administrator* (page 67).

**Related Documents**

- *Authentication* (page 6)
- *Security* (page 3)
- *Use x.509 Certificate for Membership Authentication* (page 46)

**Enable Authentication after Creating the User Administrator**

**Overview**

Enabling authentication on a MongoDB instance restricts access to the instance by requiring that users identify themselves when connecting. In this procedure, you will create the instance’s first user, which must be a user administrator and then enable authentication. Then, you can authenticate as the user administrator to create additional users and grant additional access to the instance.

This procedures outlines how enable authentication after creating the user administrator. The approach requires a restart. To enable authentication without restarting, see *Enable Client Access Control* (page 40).
Considerations

This document outlines a procedure for enabling authentication for MongoDB instance where you create the first user on an existing MongoDB system that does not require authentication before restarting the instance and requiring authentication. You can use the localhost exception (page 9) to gain access to a system with no users and authentication enabled. See Enable Client Access Control (page 40) for the description of that procedure.

Procedure

Step 1: Start the MongoDB instance without authentication. Start the mongod or mongos instance without the authorization or keyFile setting. For example:

```
mongod --port 27017 --dbpath /data/db1
```

For details on starting a mongod or mongos, see http://docs.mongodb.org/manual/tutorial/manage-mongodb-processes or http://docs.mongodb.org/manual/tutorial/deploy-shard-cluster.

Step 2: Create the system user administrator. Add the user with the userAdminAnyDatabase (page 92) role, and only that role.

The following example creates the user siteUserAdmin user on the admin database:

```
use admin
db.createUser(
    {
        user: "siteUserAdmin",
        pwd: "password",
        roles: [ { role: "userAdminAnyDatabase", db: "admin" } ]
    }
)
```

Step 3: Re-start the MongoDB instance with authentication enabled. Re-start the mongod or mongos instance with the authorization or keyFile setting. Use authorization on a standalone instance. Use keyFile on an instance in a replica set or sharded cluster.

The following example enables authentication on a standalone mongod using the authorization command-line option:

```
mongod --auth --config /etc/mongodb/mongodb.conf
```

Step 4: Create additional users. Log in with the user administrator’s credentials and create additional users. See Manage User and Roles (page 69).

Next Steps

If you need to disable authentication for any reason, restart the process without the authorization or keyFile option.
Use x.509 Certificates to Authenticate Clients

New in version 2.6.

MongoDB supports x.509 certificate authentication for use with a secure TLS/SSL connection (page 26). The x.509 client authentication allows clients to authenticate to servers with certificates (page 44) rather than with a username and password.

To use x.509 authentication for the internal authentication of replica set/sharded cluster members, see Use x.509 Certificate for Membership Authentication (page 46).

Prerequisites

Important: A full description of TLS/SSL, PKI (Public Key Infrastructure) certificates, in particular x.509 certificates, and Certificate Authority is beyond the scope of this document. This tutorial assumes prior knowledge of TLS/SSL as well as access to valid x.509 certificates.

Certificate Authority For production use, your MongoDB deployment should use valid certificates generated and signed by a single certificate authority. You or your organization can generate and maintain an independent certificate authority, or use certificates generated by a third-party SSL vendor. Obtaining and managing certificates is beyond the scope of this documentation.

Client x.509 Certificate The client certificate must have the following properties:

- A single Certificate Authority (CA) must issue the certificates for both the client and the server.
- Client certificates must contain the following fields:
  - keyUsage = digitalSignature
  - extendedKeyUsage = clientAuth
- Each unique MongoDB user must have a unique certificate.
- A client x.509 certificate’s subject, which contains the Distinguished Name (DN), must differ from that of a Member x.509 Certificate (page 46). Specifically, the subjects must differ with regards to at least one of the following attributes: Organization (O), the Organizational Unit (OU) or the Domain Component (DC).

Warning: If a client x.509 certificate’s subject has the same O, OU, and DC combination as the Member x.509 Certificate (page 46), the client will be identified as a cluster member and granted full permission on the system.

Procedures

Configure MongoDB Server

Use Command-line Options You can configure the MongoDB server from the command line, e.g.:

```
mongod --clusterAuthMode x509 --sslMode requireSSL --sslPEMKeyFile <path to SSL certificate and key PEM file>
```
Warning: If the `--sslCAFile` option and its target file are not specified, x.509 client and member authentication will not function. `mongod` and `mongos` in sharded systems, will not be able to verify the certificates of processes connecting to it against the trusted certificate authority (CA) that issued them, breaking the certificate chain.

As of version 2.6.4, `mongod` will not start with x.509 authentication enabled if the CA file is not specified.

Use Configuration File  You may also specify these options in the configuration file.

Starting in MongoDB 2.6, you can specify the configuration for MongoDB in YAML format, e.g.:

```yaml
security:
  clusterAuthMode: x509
net:
  ssl:
    mode: requireSSL
    PEMKeyFile: <path to TLS/SSL certificate and key PEM file>
    CAFile: <path to root CA PEM file>
```

For backwards compatibility, you can also specify the configuration using the older configuration file format\(^{60}\), e.g.:

```plaintext
clusterAuthMode = x509
sslMode = requireSSL
sslPEMKeyFile = <path to TLS/SSL certificate and key PEM file>
sslCAFile = <path to the root CA PEM file>
```

Include any additional options, TLS/SSL or otherwise, that are required for your specific configuration.

Add x.509 Certificate subject as a User  To authenticate with a client certificate, you must first add the value of the subject from the client certificate as a MongoDB user. Each unique x.509 client certificate corresponds to a single MongoDB user; i.e. you cannot use a single client certificate to authenticate more than one MongoDB user.

1. You can retrieve the subject from the client certificate with the following command:

   ```bash
   openssl x509 -in <pathToClient PEM> -inform PEM -subject -nameopt RFC2253
   ```

   The command returns the subject string as well as certificate:

   ```plaintext
   subject= CN=myName,OU=myOrgUnit,O=myOrg,L=myLocality,ST=myState,C=myCountry
   -----BEGIN CERTIFICATE-----
   # ...
   -----END CERTIFICATE-----
   ```

2. Add the value of the subject, omitting the spaces, from the certificate as a user.

   For example, in the `mongo` shell, to add the user with both the `readWrite` role in the `test` database and the `userAdminAnyDatabase` role which is defined only in the `admin` database:

   ```javascript
   db.getSiblingDB("$external").runCommand({
     createUser: "CN=myName,OU=myOrgUnit,O=myOrg,L=myLocality,ST=myState,C=myCountry",
     roles: [
       { role: 'readWrite', db: 'test' },
       { role: 'userAdminAnyDatabase', db: 'admin' }
     ],
     writeConcern: { w: "majority", wtimeout: 5000 }
   })
   ```

\(^{60}\)http://docs.mongodb.org/v2.4/reference/configuration-options
In the above example, to add the user with the readWrite role in the test database, the role specification document specified ‘test’ in the db field. To add userAdminAnyDatabase role for the user, the above example specified ‘admin’ in the db field.

**Note:** Some roles are defined only in the admin database, including: clusterAdmin, readAnyDatabase, readWriteAnyDatabase, dbAdminAnyDatabase, and userAdminAnyDatabase. To add a user with these roles, specify ‘admin’ in the db.

See Manage User and Roles (page 69) for details on adding a user with roles.

**Authenticate with a x.509 Certificate**

To authenticate with a client certificate, you must first add a MongoDB user that corresponds to the client certificate. See Add x.509 Certificate subject as a User (page 45).

To authenticate, use the db.auth() method in the $external database, specifying "MONGODB-X509" for the mechanism field, and the user that corresponds to the client certificate (page 45) for the user field.

For example, if using the mongo shell,

1. Connect mongo shell to the mongod set up for SSL:
   
   ```
   mongo --ssl --sslPEMKeyFile <path to CA signed client PEM file> --sslCAFile <path to root CA PEM file>
   ```

2. To perform the authentication, use the db.auth() method in the $external database. For the mechanism field, specify "MONGODB-X509", and for the user field, specify the user, or the subject, that corresponds to the client certificate.

   ```
   db.getSiblingDB("$external").auth(
   {
       mechanism: "MONGODB-X509",
       user: "CN=myName,OU=myOrgUnit,O=myOrg,L=myLocality,ST=myState,C=myCountry"
   }
   )
   ```

**Use x.509 Certificate for Membership Authentication**

New in version 2.6.

MongoDB supports x.509 certificate authentication for use with a secure TLS/SSL connection (page 26). Sharded cluster members and replica set members can use x.509 certificates to verify their membership to the cluster or the replica set instead of using keyfiles (page 6). The membership authentication is an internal process.

For client authentication with x.509, see Use x.509 Certificates to Authenticate Clients (page 44).

**Important:** A full description of TLS/SSL, PKI (Public Key Infrastructure) certificates, in particular x.509 certificates, and Certificate Authority is beyond the scope of this document. This tutorial assumes prior knowledge of TLS/SSL as well as access to valid x.509 certificates.

**Member x.509 Certificate**

The member certificate, used for internal authentication to verify membership to the sharded cluster or a replica set, must have the following properties:
• A single Certificate Authority (CA) must issue all the x.509 certificates for the members of a sharded cluster or a replica set.

• The Distinguished Name (DN), found in the member certificate’s subject, must specify a non-empty value for at least one of the following attributes: Organization (O), the Organizational Unit (OU) or the Domain Component (DC).

• The Organization attributes (O’s), the Organizational Unit attributes (OU’s), and the Domain Components (DC’s) must match those from the certificates for the other cluster members. To match, the certificate must match all specifications of these attributes, or even the non-specification of these attributes. The order of the attributes does not matter.

In the following example, the two DN’s contain matching specifications for O, OU as well as the non-specification of the DC attribute.

\[\text{CN=host1,OU=Dept1,O=MongoDB,ST=NY,C=US} \]
\[\text{C=US, ST=CA, O=MongoDB, OU=Dept1, CN=host2} \]

However, the following two DN’s contain a mismatch for the OU attribute since one contains two OU specifications and the other, only one specification.

\[\text{CN=host1,OU=Dept1,OU=Sales,O=MongoDB} \]
\[\text{CN=host2,OU=Dept1,O=MongoDB} \]

• Either the Common Name (CN) or one of the Subject Alternative Name (SAN) entries must match the hostname of the server, used by the other members of the cluster.

For example, the certificates for a cluster could have the following subjects:

\[\text{subject= CN=<myhostname1>,OU=Dept1,O=MongoDB,ST=NY,C=US} \]
\[\text{subject= CN=<myhostname2>,OU=Dept1,O=MongoDB,ST=NY,C=US} \]
\[\text{subject= CN=<myhostname3>,OU=Dept1,O=MongoDB,ST=NY,C=US} \]

You can use an x509 certificate that does not have Extended Key Usage (EUK) attributes set. If you use EKU attribute in the PEMKeyFile certificate, then specify the clientAuth and/or serverAuth attributes (i.e. “TLS Web Client Authentication” and “TLS Web Server Authentication.”) as needed. The certificate that you specify for the PEMKeyFile option requires the serverAuth attribute, and the certificate you specify to clusterFile requires the clientAuth attribute. If you omit ClusterFile, mongod will use the certificate specified to PEMKeyFile for member authentication.

Configure Replica Set/Sharded Cluster

Use Command-line Options To specify the x.509 certificate for internal cluster member authentication, append the additional TLS/SSL options --clusterAuthMode and --sslClusterFile, as in the following example for a member of a replica set:

\[\text{mongod --replSet <name> --sslMode requireSSL --clusterAuthMode x509 --sslClusterFile <path to membership certificate and key PEM file> --sslPEMKeyFile <path to SSL certificate and key PEM file> --sslCAFile <path to root CA PEM file>} \]

Include any additional options, TLS/SSL or otherwise, that are required for your specific configuration. For instance, if the membership key is encrypted, set the --sslClusterPassword to the passphrase to decrypt the key or have MongoDB prompt for the passphrase. See SSL Certificate Passphrase (page 30) for details.

**Warning:** If the --sslCAFile option and its target file are not specified, x.509 client and member authentication will not function. mongod, and mongos in sharded systems, will not be able to verify the certificates of processes connecting to it against the trusted certificate authority (CA) that issued them, breaking the certificate chain.

As of version 2.6.4, mongod will not start with x.509 authentication enabled if the CA file is not specified.
Use Configuration File  You can specify the configuration for MongoDB in a YAML formatted configuration file, as in the following example:

```
security:
  clusterAuthMode: x509
net:
  mode: requireSSL
  PEMKeyFile: <path to TLS/SSL certificate and key PEM file>
  CAFile: <path to root CA PEM file>
  clusterFile: <path to x.509 membership certificate and key PEM file>
```

*See* `security.clusterAuthMode`, `net.ssl.mode`, `net.ssl.PEMKeyFile`, `net.ssl.CAFile`, and `net.ssl.clusterFile` *for more information on the settings.*

Upgrade from Keyfile Authentication to x.509 Authentication

To upgrade clusters that are currently using keyfile authentication to x.509 authentication, use a rolling upgrade process.

Clusters Currently Using TLS/SSL  For clusters using TLS/SSL and keyfile authentication, to upgrade to x.509 cluster authentication, use the following rolling upgrade process:

1. For each node of a cluster, start the node with the option `--clusterAuthMode` set to `sendKeyFile` and the option `--sslClusterFile` set to the appropriate path of the node’s certificate. Include other TLS/SSL options (page 26) as well as any other options that are required for your specific configuration. For example:

   ```
   mongod --replSet <name> --sslMode requireSSL --clusterAuthMode sendKeyFile --sslClusterFile <path to membership certificate and key PEM file> --sslPEMKeyFile <path to SSL Certificate and key PEM file> --sslCAFile <path to root CA PEM file>
   ```

   With this setting, each node continues to use its keyfile to authenticate itself as a member. However, each node can now accept either a keyfile or an x.509 certificate from other members to authenticate those members. Upgrade all nodes of the cluster to this setting.

2. Then, for each node of a cluster, connect to the node and use the `setParameter` command to update the `clusterAuthMode` to `sendX509`. For example,

   ```
   db.getSiblingDB('admin').runCommand( { setParameter: 1, clusterAuthMode: "sendX509" } )
   ```

   With this setting, each node uses its x.509 certificate, specified with the `--sslClusterFile` option in the previous step, to authenticate itself as a member. However, each node continues to accept either a keyfile or an x.509 certificate from other members to authenticate those members. Upgrade all nodes of the cluster to this setting.

3. Optional but recommended. Finally, for each node of the cluster, connect to the node and use the `setParameter` command to update the `clusterAuthMode` to `x509` to only use the x.509 certificate for authentication. For example:

   ```
   db.getSiblingDB('admin').runCommand( { setParameter: 1, clusterAuthMode: "x509" } )
   ```

   After the upgrade of all nodes, edit the configuration file with the appropriate x.509 settings to ensure that upon subsequent restarts, the cluster uses x.509 authentication.

*See* `--clusterAuthMode` *for the various modes and their descriptions.*

---

61 As an alternative to using the `setParameter` command, you can also restart the nodes with the appropriate TLS/SSL and x509 options and values.
Clusters Currently Not Using TLS/SSL  For clusters using keyfile authentication but not TLS/SSL, to upgrade to x.509 authentication, use the following rolling upgrade process:

1. For each node of a cluster, start the node with the option --sslMode set to allowSSL, the option --clusterAuthMode set to sendKeyFile and the option --sslClusterFile set to the appropriate path of the node’s certificate. Include other TLS/SSL options (page 26) as well as any other options that are required for your specific configuration. For example:

   mongod --replSet <name> --sslMode allowSSL --clusterAuthMode sendKeyFile --sslClusterFile <path to membership certificate and key PEM file>

   The --sslMode allowSSL setting allows the node to accept both TLS/SSL and non-TLS/non-SSL incoming connections. Its outgoing connections do not use TLS/SSL.

   The --clusterAuthMode sendKeyFile setting allows each node continues to use its keyfile to authenticate itself as a member. However, each node can now accept either a keyfile or an x.509 certificate from other members to authenticate those members.

   Upgrade all nodes of the cluster to these settings.

2. Then, for each node of a cluster, connect to the node and use the setParameter command to update the sslMode to preferSSL and the clusterAuthMode to sendX509. For example:

   db.getSiblingDB('admin').runCommand( { setParameter: 1, sslMode: "preferSSL", clusterAuthMode: "sendX509" } )

   With the sslMode set to preferSSL, the node accepts both TLS/SSL and non-TLS/non-SSL incoming connections, and its outgoing connections use TLS/SSL.

   With the clusterAuthMode set to sendX509, each node uses its x.509 certificate, specified with the --sslClusterFile option in the previous step, to authenticate itself as a member. However, each node continues to accept either a keyfile or an x.509 certificate from other members to authenticate those members.

   Upgrade all nodes of the cluster to these settings.

3. Optional but recommended. Finally, for each node of the cluster, connect to the node and use the setParameter command to update the sslMode to requireSSL and the clusterAuthMode to x509. For example:

   db.getSiblingDB('admin').runCommand( { setParameter: 1, sslMode: "requireSSL", clusterAuthMode: "x509" } )

   With the sslMode set to requireSSL, the node only uses TLS/SSLs connections.

   With the clusterAuthMode set to x509, the node only uses the x.509 certificate for authentication.

4. After the upgrade of all nodes, edit the configuration file with the appropriate TLS/SSL and x.509 settings to ensure that upon subsequent restarts, the cluster uses x.509 authentication.

   See --clusterAuthMode for the various modes and their descriptions.

Authenticate Using SASL and LDAP with ActiveDirectory

MongoDB Enterprise provides support for proxy authentication of users. This allows administrators to configure a MongoDB cluster to authenticate users by proxying authentication requests to a specified Lightweight Directory Access Protocol (LDAP) service.

Considerations

MongoDB Enterprise for Windows does not include LDAP support for authentication. However, MongoDB Enterprise for Linux supports using LDAP authentication with an ActiveDirectory server.
MongoDB does not support LDAP authentication in mixed sharded cluster deployments that contain both version 2.4 and version 2.6 shards. See http://docs.mongodb.org/manual/release-notes/2.6-upgrade for upgrade instructions.

Use secure encrypted or trusted connections between clients and the server, as well as between `saslauthd` and the LDAP server. The LDAP server uses the SASL PLAIN mechanism, sending and receiving data in plain text. You should use only a trusted channel such as a VPN, a connection encrypted with TLS/SSL, or a trusted wired network.

**Configure `saslauthd`**

LDAP support for user authentication requires proper configuration of the `saslauthd` daemon process as well as the MongoDB server.

**Step 1: Specify the mechanism.** On systems that configure `saslauthd` with the `/etc/sysconfig/saslauthd` file, such as Red Hat Enterprise Linux, Fedora, CentOS, and Amazon Linux AMI, set the mechanism `MECH` to `ldap`:

```bash
MECH=ldap
```

On systems that configure `saslauthd` with the `/etc/default/saslauthd` file, such as Ubuntu, set the `MECHANISMS` option to `ldap`:

```bash
MECHANISMS="ldap"
```

**Step 2: Adjust caching behavior.** On certain Linux distributions, `saslauthd` starts with the caching of authentication credentials enabled. Until restarted or until the cache expires, `saslauthd` will not contact the LDAP server to re-authenticate users in its authentication cache. This allows `saslauthd` to successfully authenticate users in its cache, even in the LDAP server is down or if the cached users’ credentials are revoked.

To set the expiration time (in seconds) for the authentication cache, see the `-t` option of `saslauthd`.

**Step 3: Configure LDAP Options with ActiveDirectory.** If the `saslauthd.conf` file does not exist, create it. The `saslauthd.conf` file usually resides in the `/etc` folder. If specifying a different file path, see the `-O` option of `saslauthd`.

To use with ActiveDirectory, start `saslauthd` with the following configuration options set in the `saslauthd.conf` file:

```bash
ldap_servers: <ldap uri>
ldap_use_sasl: yes
ldap_mech: DIGEST-MD5
ldap_auth_method: fastbind
```

For the `<ldap uri>`, specify the uri of the ldap server. For example, `ldap_servers: ldaps://ad.example.net`.

For more information on `saslauthd` configuration, see http://www.openldap.org/doc/admin24/guide.html#Configuringsaslauthd.

**Step 4: Test the `saslauthd` configuration.** Use `testsaslauthd` utility to test the `saslauthd` configuration. For example:

63 http://www.linuxcommand.org/man_pages/saslauthd8.html
Configure MongoDB

Step 1: Add user to MongoDB for authentication. Add the user to the $external database in MongoDB. To specify the user’s privileges, assign roles (page 14) to the user.

For example, the following adds a user with read-only access to the records database.

```javascript
db.getSiblingDB("$external").createUser(
   {
       user : <username>,
       roles: [ { role: "read", db: "records" } ]
   }
)
```

Add additional principals as needed. For more information about creating and managing users, see http://docs.mongodb.org/manual/reference/command/nav-user-management.

Step 2: Configure MongoDB server. To configure the MongoDB server to use the saslauthd instance for proxy authentication, start the mongod with the following options:

- `--auth`,
- `authenticationMechanisms` parameter set to PLAIN, and
- `saslauthdPath` parameter set to the path to the Unix-domain Socket of the saslauthd instance.

Configure the MongoDB server using either the command line option `--setParameter` or the configuration file. Specify additional configurations as appropriate for your configuration.

If you use the `authorization` option to enforce authentication, you will need privileges to create a user.

Use specific saslauthd socket path. For socket path of `/<some>/<path>/saslauthd`, set the `saslauthdPath` to `/<some>/<path>/saslauthd/mux`, as in the following command line example:

```bash
mongod --auth --setParameter saslauthdPath=/<some>/<path>/saslauthd/mux --setParameter authenticationMechanisms=PLAIN
```

Or if using a YAML format configuration file, specify the following settings in the file:

```yaml
security:
   authorization: enabled

setParameter:
   saslauthdPath: /<some>/<path>/saslauthd/mux
   authenticationMechanisms: PLAIN
```

Or, if using the older configuration file format:

```yaml
auth=true
setParameter=saslauthdPath=/<some>/<path>/saslauthd/mux
setParameter=authenticationMechanisms=PLAIN
```

Note: /var/run/saslauthd directory must have permissions set to 755 for MongoDB to successfully authenticate.
Use default Unix-domain socket path. To use the default Unix-domain socket path, set the `saslauthdPath` to the empty string "", as in the following command line example:

```sh
mongod --auth --setParameter saslauthdPath="" --setParameter authenticationMechanisms=PLAIN
```

Or if using a YAML format configuration file, specify the following settings in the file:

```yaml
security:
  authorization: enabled

setParameter:
  saslauthdPath: ""
  authenticationMechanisms: PLAIN
```

Or, if using the older configuration file format:

```yaml
auth=true
setParameter=saslauthdPath=""
setParameter=authenticationMechanisms=PLAIN
```

Step 3: Authenticate the user in the `mongo` shell. To perform the authentication in the `mongo` shell, use the `db.auth()` method in the `$external` database.

Specify the value "PLAIN" in the mechanism field, the user and password in the user and pwd fields respectively, and the value false in the digestPassword field. You must specify false for digestPassword since the server must receive an undigested password to forward on to saslauthd, as in the following example:

```javascript
db.getSiblingDB("$external").auth(
  {
    mechanism: "PLAIN",
    user: <username>,
    pwd: <cleartext password>,
    digestPassword: false
  }
)
```

The server forwards the password in plain text. In general, use only on a trusted channel (VPN, TLS/SSL, trusted wired network). See Considerations.

Authenticate Using SASL and LDAP with OpenLDAP

MongoDB Enterprise provides support for proxy authentication of users. This allows administrators to configure a MongoDB cluster to authenticate users by proxying authentication requests to a specified Lightweight Directory Access Protocol (LDAP) service.

Considerations

MongoDB Enterprise for Windows does not include LDAP support for authentication. However, MongoDB Enterprise for Linux supports using LDAP authentication with an ActiveDirectory server.

MongoDB does not support LDAP authentication in mixed sharded cluster deployments that contain both version 2.4 and version 2.6 shards. See [http://docs.mongodb.org/manual/release-notes/2.6-upgrade](http://docs.mongodb.org/manual/release-notes/2.6-upgrade) for upgrade instructions.

---

65http://docs.mongodb.org/v2.4/reference/configuration-options
Use secure encrypted or trusted connections between clients and the server, as well as between `saslauthd` and the LDAP server. The LDAP server uses the SASL PLAIN mechanism, sending and receiving data in **plain text**. You should use only a trusted channel such as a VPN, a connection encrypted with TLS/SSL, or a trusted wired network.

**Configure `saslauthd`**

LDAP support for user authentication requires proper configuration of the `saslauthd` daemon process as well as the MongoDB server.

**Step 1: Specify the mechanism.** On systems that configure `saslauthd` with the `/etc/sysconfig/saslauthd` file, such as Red Hat Enterprise Linux, Fedora, CentOS, and Amazon Linux AMI, set the mechanism `MECH` to `ldap`:

```
MECH=ldap
```

On systems that configure `saslauthd` with the `/etc/default/saslauthd` file, such as Ubuntu, set the `MECHANISMS` option to `ldap`:

```
MECHANISMS="ldap"
```

**Step 2: Adjust caching behavior.** On certain Linux distributions, `saslauthd` starts with the caching of authentication credentials **enabled**. Until restarted or until the cache expires, `saslauthd` will not contact the LDAP server to re-authenticate users in its authentication cache. This allows `saslauthd` to successfully authenticate users in its cache, even in the LDAP server is down or if the cached users’ credentials are revoked.

To set the expiration time (in seconds) for the authentication cache, see the `-t` option\(^66\) of `saslauthd`.

**Step 3: Configure LDAP Options with OpenLDAP.** If the `saslauthd.conf` file does not exist, create it. The `saslauthd.conf` file usually resides in the `/etc` folder. If specifying a different file path, see the `-O` option\(^67\) of `saslauthd`.

To connect to an OpenLDAP server, update the `saslauthd.conf` file with the following configuration options:

```
ldap_servers: <ldap uri>
ldap_search_base: <search base>
ldap_filter: <filter>
```

The `ldap_servers` specifies the uri of the LDAP server used for authentication. In general, for OpenLDAP installed on the local machine, you can specify the value `ldap://localhost:389` or if using LDAP over TLS/SSL, you can specify the value `ldaps://localhost:636`.

The `ldap_search_base` specifies distinguished name to which the search is relative. The search includes the base or objects below.

The `ldap_filter` specifies the search filter.

The values for these configuration options should correspond to the values specific for your test. For example, to filter on email, specify `ldap_filter: (mail=%n)` instead.

**OpenLDAP Example** A sample `saslauthd.conf` file for OpenLDAP includes the following content:

ldap_servers: ldaps://ad.example.net
ldap_search_base: ou=Users,dc=example,dc=com
ldap_filter: (uid=%u)

To use this sample OpenLDAP configuration, create users with a uid attribute (login name) and place under the Users organizational unit (ou) under the domain components (dc) example and com.

For more information on saslauthd configuration, see http://www.openldap.org/doc/admin24/guide.html#Configuringsaslauthd.

Step 4: Test the saslauthd configuration. Use testsaslauthd utility to test the saslauthd configuration. For example:

testsaslauthd -u testuser -p testpassword -f /var/run/saslauthd/mux

Note: /var/run/saslauthd directory must have permissions set to 755 for MongoDB to successfully authenticate.

Configure MongoDB

Step 1: Add user to MongoDB for authentication. Add the user to the $external database in MongoDB. To specify the user’s privileges, assign roles (page 14) to the user.

For example, the following adds a user with read-only access to the records database.

db.getSiblingDB("$external").createUser(
  |
  user : <username>,
  roles: [ { role: "read", db: "records" } ]
)

Add additional principals as needed. For more information about creating and managing users, see http://docs.mongodb.org/manual/reference/command/nav-user-management.

Step 2: Configure MongoDB server. To configure the MongoDB server to use the saslauthd instance for proxy authentication, start the mongod with the following options:

• --auth,
• authenticationMechanisms parameter set to PLAIN, and
• saslauthdPath parameter set to the path to the Unix-domain Socket of the saslauthd instance.

Configure the MongoDB server using either the command line option --setParameter or the configuration file. Specify additional configurations as appropriate for your configuration.

If you use the authorization option to enforce authentication, you will need privileges to create a user.

Use specific saslauthd socket path. For socket path of /<some>/<path>/saslauthd, set the saslauthdPath to /<some>/<path>/saslauthd/mux, as in the following command line example:

mongod --auth --setParameter saslauthdPath=/<some>/<path>/saslauthd/mux --setParameter authenticationMechanisms=PLAIN

Or if using a YAML format configuration file, specify the following settings in the file:
security:
  authorization: enabled

setParameter:
  saslauthdPath: /<some>/<path>/saslauthd/mux
  authenticationMechanisms: PLAIN

Or, if using the older configuration file format:

auth=true
setParameter=saslauthdPath=/<some>/<path>/saslauthd/mux
setParameter=authenticationMechanisms=PLAIN

Use default Unix-domain socket path. To use the default Unix-domain socket path, set the `saslauthdPath` to the empty string " ", as in the following command line example:

```bash
mongod --auth --setParameter saslauthdPath="" --setParameter authenticationMechanisms=PLAIN
```

Or if using a YAML format configuration file, specify the following settings in the file:

```yaml
security:
  authorization: enabled

setParameter:
  saslauthdPath: ""
  authenticationMechanisms: PLAIN
```

Or, if using the older configuration file format:

```text
auth=true
setParameter=saslauthdPath=""
setParameter=authenticationMechanisms=PLAIN
```

Step 3: Authenticate the user in the `mongo` shell. To perform the authentication in the `mongo` shell, use the `db.auth()` method in the `$external` database.

Specify the value "PLAIN" in the `mechanism` field, the user and password in the `user` and `pwd` fields respectively, and the value `false` in the `digestPassword` field. You must specify `false` for `digestPassword` since the server must receive an undigested password to forward on to `saslauthd`, as in the following example:

```javascript
db.getSiblingDB("$external").auth(
{
  mechanism: "PLAIN",
  user: <username>,
  pwd: <cleartext password>,
  digestPassword: false
}
)
```

The server forwards the password in plain text. In general, use only on a trusted channel (VPN, TLS/SSL, trusted wired network). See Considerations.

**Configure MongoDB with Kerberos Authentication on Linux**

New in version 2.4.

68 [http://docs.mongodb.org/v2.4/reference/configuration-options](http://docs.mongodb.org/v2.4/reference/configuration-options)
69 [http://docs.mongodb.org/v2.4/reference/configuration-options](http://docs.mongodb.org/v2.4/reference/configuration-options)
Overview

MongoDB Enterprise supports authentication using a Kerberos service (page 11). Kerberos is an industry standard authentication protocol for large client/server system.

Prerequisites

Setting up and configuring a Kerberos deployment is beyond the scope of this document. This tutorial assumes you have configured a Kerberos service principal (page 12) for each mongod and mongos instance in your MongoDB deployment, and you have a valid keytab file (page 12) for each mongod and mongos instance.

To verify MongoDB Enterprise binaries:

```
mongod --version
```

In the output from this command, look for the string `modules: subscription` or `modules: enterprise` to confirm your system has MongoDB Enterprise.

Procedure

The following procedure outlines the steps to add a Kerberos user principal to MongoDB, configure a standalone mongod instance for Kerberos support, and connect using the mongo shell and authenticate the user principal.

**Step 1: Start mongod without Kerberos.** For the initial addition of Kerberos users, start mongod without Kerberos support.

If a Kerberos user is already in MongoDB and has the privileges required to create a user, you can start mongod with Kerberos support.

**Step 2: Connect to mongod.** Connect via the mongo shell to the mongod instance. If mongod has `--auth` enabled, ensure you connect with the privileges required to create a user.

**Step 3: Add Kerberos Principal(s) to MongoDB.** Add a Kerberos principal, `<username>@<KERBEROS REALM>` or `<username>/<instance>@<KERBEROS REALM>`, to MongoDB in the `$external` database. Specify the Kerberos realm in all uppercase. The `$external` database allows mongod to consult an external source (e.g. Kerberos) to authenticate. To specify the user’s privileges, assign `roles` (page 14) to the user.

The following example adds the Kerberos principal `application/reporting@EXAMPLE.NET` with read-only access to the `records` database:

```
use $external
db.createUser(
    {
        user: "application/reporting@EXAMPLE.NET",
        roles: [ { role: "read", db: "records" } ]
    }
)
```

Add additional principals as needed. For every user you want to authenticate using Kerberos, you must create a corresponding user in MongoDB. For more information about creating and managing users, see [http://docs.mongodb.org/manual/reference/command/nav-user-management](http://docs.mongodb.org/manual/reference/command/nav-user-management).
Step 4: Start `mongod` with Kerberos support. To start `mongod` with Kerberos support, set the environmental variable `KRB5_KTNAME` to the path of the keytab file and the `mongod` parameter `authenticationMechanisms` to `GSSAPI` in the following form:

```
env
  KRB5_KTNAME=<path to keytab file> \
  mongod \
  --setParameter authenticationMechanisms=GSSAPI
<additional mongod options>
```

For example, the following starts a standalone `mongod` instance with Kerberos support:

```
env
  KRB5_KTNAME=/opt/mongodb/mongod.keytab \
  /opt/mongodb/bin/mongod  --auth \
  --setParameter authenticationMechanisms=GSSAPI \
  --dbpath /opt/mongodb/data
```

The path to your `mongod` as well as your keytab file (page 12) may differ. Modify or include additional `mongod` options as required for your configuration. The keytab file (page 12) must be only accessible to the owner of the `mongod` process.

With the official .deb or .rpm packages, you can set the `KRB5_KTNAME` in a environment settings file. See `KRB5_KTNAME` (page 57) for details.

Step 5: Connect `mongo` shell to `mongod` and authenticate. Connect the `mongo` shell client as the Kerberos principal `application/reporting@EXAMPLE.NET`. Before connecting, you must have used Kerberos's `kinit` program to get credentials for `application/reporting@EXAMPLE.NET`.

You can connect and authenticate from the command line.

```
mongo
  --authenticationMechanism=GSSAPI
  --authenticationDatabase='$external'
  --username application/reporting@EXAMPLE.NET
```

Or, alternatively, you can first connect `mongo` to the `mongod`, and then from the `mongo` shell, use the `db.auth()` method to authenticate in the `$external` database.

```
use $external
db.auth( { mechanism: "GSSAPI", user: "application/reporting@EXAMPLE.NET" } )
```

Additional Considerations

**KRB5_KTNAME** If you installed MongoDB Enterprise using one of the official .deb or .rpm packages, and you use the included init/upstart scripts to control the `mongod` instance, you can set the `KRB5_KTNAME` variable in the default environment settings file instead of setting the variable each time.

For .rpm packages, the default environment settings file is `/etc/sysconfig/mongod`

For .deb packages, the file is `/etc/default/mongodb`

Set the `KRB5_KTNAME` value in a line that resembles the following:

```
export
  KRB5_KTNAME="<path to keytab>"
```

Configure `mongos` for Kerberos To start `mongos` with Kerberos support, set the environmental variable `KRB5_KTNAME` to the path of its keytab file (page 12) and the `mongos` parameter `authenticationMechanisms` to `GSSAPI` in the following form:
env KRB5_KTNAME=<path to keytab file> \
mongos \
--setParameter authenticationMechanisms=GSSAPI \
<additional mongos options>

For example, the following starts a mongos instance with Kerberos support:

env KRB5_KTNAME=/opt/mongodb/mongos.keytab \
mongos \
--setParameter authenticationMechanisms=GSSAPI \
--configdb shard0.example.net, shard1.example.net,shard2.example.net \
--keyFile /opt/mongodb/mongos.keyfile

The path to your mongos as well as your keytab file (page 12) may differ. The keytab file (page 12) must be only accessible to the owner of the mongos process.

Modify or include any additional mongos options as required for your configuration. For example, instead of using --keyFile for internal authentication of sharded cluster members, you can use x.509 member authentication (page 46) instead.

Use a Config File To configure mongod or mongos for Kerberos support using a configuration file, specify the authenticationMechanisms setting in the configuration file:

If using the YAML configuration file format:

setParameter:
  authenticationMechanisms: GSSAPI

Or, if using the older .ini configuration file format:

setParameter=authenticationMechanisms=GSSAPI

Modify or include any additional mongod options as required for your configuration. For example, if /opt/mongodb/mongod.conf contains the following configuration settings for a standalone mongod:

security:
  authorization: enabled
setParameter:
  authenticationMechanisms: GSSAPI
storage:
  dbPath: /opt/mongodb/data

Or, if using the older configuration file format:

auth = true
setParameter=authenticationMechanisms=GSSAPI
dbpath=/opt/mongodb/data

To start mongod with Kerberos support, use the following form:

env KRB5_KTNAME=/opt/mongodb/mongod.keytab \
/opt/mongodb/bin/mongod --config /opt/mongodb/mongod.conf

The path to your mongod, keytab file (page 12), and configuration file may differ. The keytab file (page 12) must be only accessible to the owner of the mongod process.

Troubleshoot Kerberos Setup for MongoDB If you encounter problems when starting mongod or mongos with Kerberos authentication, see Troubleshoot Kerberos Authentication on Linux (page 63).
Incorporate Additional Authentication Mechanisms  Kerberos authentication (GSSAPI (page 8) (Kerberos)) can work alongside MongoDB’s challenge/response authentication mechanisms (SCRAM-SHA-1 (page 6) and MONGODB-CR (page 7)), MongoDB’s authentication mechanism for LDAP (PLAIN (page 8) (LDAP SASL)), and MongoDB’s authentication mechanism for x.509 (MONGODB-X509 (page 8)). Specify the mechanisms as follows: 

```
--setParameter authenticationMechanisms=GSSAPI,SCRAM-SHA-1
```

Only add the other mechanisms if in use. This parameter setting does not affect MongoDB’s internal authentication of cluster members.

- MongoDB LDAP and Kerberos Authentication with Dell (Quest) Authentication Services
- MongoDB with Red Hat Enterprise Linux Identity Management and Kerberos

Configure MongoDB with Kerberos Authentication on Windows

New in version 2.6.

Overview

MongoDB Enterprise supports authentication using a Kerberos service (page 11). Kerberos is an industry standard authentication protocol for large client/server systems. Kerberos allows MongoDB and applications to take advantage of existing authentication infrastructure and processes.

Prerequisites

Setting up and configuring a Kerberos deployment is beyond the scope of this document. This tutorial assumes you have configured a Kerberos service principal (page 12) for each mongod.exe and mongos.exe instance.

Procedures

Step 1: Start mongod.exe without Kerberos.  
For the initial addition of Kerberos users, start mongod.exe without Kerberos support.

If a Kerberos user is already in MongoDB and has the privileges required to create a user, you can start mongod.exe with Kerberos support.

Step 2: Connect to mongod.  
Connect via the mongo.exe shell to the mongod.exe instance. If mongod.exe has --auth enabled, ensure you connect with the privileges required to create a user.

Step 3: Add Kerberos Principal(s) to MongoDB.  
Add a Kerberos principal, <username>@<KERBEROS_REALM>, to MongoDB in the $external database. Specify the Kerberos realm in ALL UPPERCASE. The $external database allows mongod.exe to consult an external source (e.g. Kerberos) to authenticate. To specify the user’s privileges, assign roles (page 14) to the user.

---

jmp=docs  
72 http://docs.mongodb.org/ecosystem/tutorial/manage-red-hat-enterprise-linux-identity-management?
jmp=docs
The following example adds the Kerberos principal `reportingapp@EXAMPLE.NET` with read-only access to the `records` database:

```javascript
use $external
db.createUser(
    {
        user: "reportingapp@EXAMPLE.NET",
        roles: [{ role: "read", db: "records" }]
    }
)
```

Add additional principals as needed. For every user you want to authenticate using Kerberos, you must create a corresponding user in MongoDB. For more information about creating and managing users, see http://docs.mongodb.org/manual/reference/command/nav-user-management.

**Step 4: Start `mongod.exe` with Kerberos support.** You must start `mongod.exe` as the *service principal account* (page 61).

To start `mongod.exe` with Kerberos support, set the `mongod.exe` parameter `authenticationMechanisms` to GSSAPI:

`mongod.exe --setParameter authenticationMechanisms=GSSAPI <additional mongod.exe options>`

For example, the following starts a standalone `mongod.exe` instance with Kerberos support:

`mongod.exe --auth --setParameter authenticationMechanisms=GSSAPI`

Modify or include additional `mongod.exe` options as required for your configuration.

**Step 5: Connect `mongo.exe` shell to `mongod.exe` and authenticate.** Connect the `mongo.exe` shell client as the Kerberos principal `application@EXAMPLE.NET`.

You can connect and authenticate from the command line:

`mongo.exe --authenticationMechanism=GSSAPI --authenticationDatabase='$external' \ --username reportingapp@EXAMPLE.NET`

Or, alternatively, you can first connect `mongo.exe` to the `mongod.exe`, and then from the `mongo.exe` shell, use the `db.auth()` method to authenticate in the `$external` database.

```javascript
use $external
db.auth({ mechanism: "GSSAPI", user: "reportingapp@EXAMPLE.NET" })
```

**Additional Considerations**

**Configure `mongos.exe` for Kerberos** To start `mongos.exe` with Kerberos support, set the `mongos.exe` parameter `authenticationMechanisms` to GSSAPI. You must start `mongos.exe` as the *service principal account* (page 61):

`mongos.exe --setParameter authenticationMechanisms=GSSAPI <additional mongos options>`

For example, the following starts a `mongos` instance with Kerberos support:

`mongos.exe --setParameter authenticationMechanisms=GSSAPI --configdb shard0.example.net, shard1.example.net, shard2.example.net --keyFile C:\path\mongos.keyfile`

Modify or include any additional `mongos.exe` options as required for your configuration. For example, instead of using `--keyFile` for internal authentication of sharded cluster members, you can use `x.509 member authentication` (page 46) instead.
Assign Service Principal Name to MongoDB Windows Service Use `setspn.exe` to assign the service principal name (SPN) to the account running the `mongod.exe` and the `mongos.exe` service:

```
setspn.exe -A <service>/<fully qualified domain name> <service account name>
```

For example, if `mongod.exe` runs as a service named `mongodb` on `testserver.mongodb.com` with the service account name `mongodtest`, assign the SPN as follows:

```
setspn.exe -A mongodb/testserver.mongodb.com mongodtest
```

Incorporate Additional Authentication Mechanisms Kerberos authentication (`GSSAPI` (page 8) (Kerberos)) can work alongside MongoDB’s challenge/response authentication mechanisms (`SCRAM-SHA-1` (page 6) and `MONGODB-CR` (page 7)), MongoDB’s authentication mechanism for LDAP (`PLAIN` (page 8) (LDAP SASL)), and MongoDB’s authentication mechanism for x.509 (`MONGODB-X509` (page 8)). Specify the mechanisms as follows:

```
--setParameter authenticationMechanisms=GSSAPI,SCRAM-SHA-1
```

Only add the other mechanisms if in use. This parameter setting does not affect MongoDB’s internal authentication of cluster members.

Authenticate to a MongoDB Instance or Cluster

Overview

To authenticate to a running `mongod` or `mongos` instance, you must have user credentials for a resource on that instance. When you authenticate to MongoDB, you authenticate either to a database or to a cluster. Your user privileges determine the resource you can authenticate to.

You authenticate to a resource either by:

- using the authentication options when connecting to the `mongod` or `mongos` instance, or
- connecting first and then authenticating to the resource with the `authenticate` command or the `db.auth()` method.

This section describes both approaches.

In general, always use a trusted channel (VPN, TLS/SSL, trusted wired network) for connecting to a MongoDB instance.

Prerequisites

You must have user credentials on the database or cluster to which you are authenticating.

Procedures

Authenticate When First Connecting to MongoDB

Step 1: Specify your credentials when starting the `mongo` instance. When using `mongo` to connect to a `mongod` or `mongos`, enter your username, password, and `authenticationDatabase`. For example:

```
mongo --username "prodManager" --password "cleartextPassword" --authenticationDatabase 'products'
```
Step 2: Close the session when your work is complete. To close an authenticated session, use the `logout` command:

```javascript
db.runCommand( { logout: 1 } )
```

Authenticate After Connecting to MongoDB

Step 1: Connect to a MongoDB instance. Connect to a `mongod` or `mongos` instance.

Step 2: Switch to the database to which to authenticate.

```javascript
use <database>
```

Step 3: Authenticate. Use either the `authenticate` command or the `db.auth()` method to provide your username and password to the database. For example:

```javascript
db.auth( "prodManager", "cleartextPassword" )
```

Step 4: Close the session when your work is complete. To close an authenticated session, use the `logout` command:

```javascript
db.runCommand( { logout: 1 } )
```

Generate a Key File

Overview

This section describes how to generate a key file to store authentication information. After generating a key file, specify the key file using the `keyFile` option when starting a `mongod` or `mongos` instance.

A key's length must be between 6 and 1024 characters and may only contain characters in the base64 set. The key file must not have group or world permissions on UNIX systems. Key file permissions are not checked on Windows systems.

MongoDB strips whitespace characters (e.g. \x0d, \x09, and \x20) for cross-platform convenience. As a result, the following operations produce identical keys:

```bash
echo -e "my secret key" > key1
echo -e "my secret key\n" > key2
echo -e "my secret key" > key3
echo -e "my\nsecret\nkey\n" > key4
```

Procedure

Step 1: Create a key file. Create the key file your deployment will use to authenticate servers to each other.

To generate pseudo-random data to use for a `keyfile`, issue the following `openssl` command:

```bash
openssl rand -base64 741 > mongodb-keyfile
chmod 600 mongodb-keyfile
```

You may generate a key file using any method you choose. Always ensure that the password stored in the key file is both long and contains a high amount of entropy. Using `openssl` in this manner helps generate such a key.
Step 2: Specify the key file when starting a MongoDB instance. Specify the path to the key file with the `keyFile` option.

Troubleshoot Kerberos Authentication on Linux

New in version 2.4.

Kerberos Configuration Checklist

If you have difficulty starting `mongod` or `mongos` with Kerberos (page 11) on Linux systems, ensure that:

- The `mongod` and the `mongos` binaries are from MongoDB Enterprise.
  
  To verify MongoDB Enterprise binaries:
  ```
  mongod --version
  ```
  
  In the output from this command, look for the string `modules: subscription` or `modules: enterprise` to confirm your system has MongoDB Enterprise.

- You are not using the HTTP Console. MongoDB Enterprise does not support Kerberos authentication over the HTTP Console interface.

- Either the service principal name (SPN) in the `keytab file` (page 12) matches the SPN for the `mongod` or `mongos` instance, or the `mongod` or the `mongos` instance use the `--setParameter saslHostName=<hostname>` to match the name in the keytab file.

- The canonical system hostname of the system that runs the `mongod` or `mongos` instance is a resolvable, fully qualified domain for this host. You can test the system hostname resolution with the `hostname -f` command at the system prompt.

- Each host that runs a `mongod` or `mongos` instance has both the A and PTR DNS records to provide forward and reverse lookup. The records allow the host to resolve the components of the Kerberos infrastructure.

- Both the Kerberos Key Distribution Center (KDC) and the system running `mongod` instance or `mongos` must be able to resolve each other using DNS. By default, Kerberos attempts to resolve hosts using the content of the `/etc/kerb5.conf` before using DNS to resolve hosts.

- The time synchronization of the systems running `mongod` or the `mongos` instances and the Kerberos infrastructure are within the maximum time skew (default is 5 minutes) of each other. Time differences greater than the maximum time skew will prevent successful authentication.

Debug with More Verbose Logs

If you still encounter problems with Kerberos on Linux, you can start both `mongod` and `mongo` (or another client) with the environment variable `KRB5_TRACE` set to different files to produce more verbose logging of the Kerberos process to help further troubleshooting. For example, the following starts a standalone `mongod` with `KRB5_TRACE` set:

```
env KRB5_KTNAME=/opt/mongodb/mongod.keytab \
    KRB5_TRACE=/opt/mongodb/log/mongodb-kerberos.log \
    /opt/mongodb/bin/mongod --dbpath /opt/mongodb/data \
    --fork --logpath /opt/mongodb/log/mongodb.log \
    --auth --setParameter authenticationMechanisms=GSSAPI
```

73 [https://docs.mongodb.org/ecosystem/tools/http-interface/#http-console](https://docs.mongodb.org/ecosystem/tools/http-interface/#http-console)
Common Error Messages

In some situations, MongoDB will return error messages from the GSSAPI interface if there is a problem with the Kerberos service. Some common error messages are:

**GSSAPI error in client while negotiating security context.** This error occurs on the client and reflects insufficient credentials or a malicious attempt to authenticate.

If you receive this error, ensure that you are using the correct credentials and the correct fully qualified domain name when connecting to the host.

**GSSAPI error acquiring credentials.** This error occurs during the start of the mongod or mongos and reflects improper configuration of the system hostname or a missing or incorrectly configured keytab file.

If you encounter this problem, consider the items in the [Kerberos Configuration Checklist](page 63), in particular, whether the SPN in the [keytab file](page 12) matches the SPN for the mongod or mongos instance.

To determine whether the SPNs match:

1. Examine the keytab file, with the following command:
   ```bash
   klist -k <keytab>
   ```
   Replace `<keytab>` with the path to your keytab file.

2. Check the configured hostname for your system, with the following command:
   ```bash
   hostname -f
   ```
   Ensure that this name matches the name in the keytab file, or start mongod or mongos with the `--setParameter saslHostName=<hostname>`.

Implement Field Level Redaction

The `$redact` pipeline operator restricts the contents of the documents based on information stored in the documents themselves.

To store the access criteria data, add a field to the documents and embedded documents. To allow for multiple combinations of access levels for the same data, consider setting the access field to an array of arrays. Each array element contains a required set that allows a user with that set to access the data.

Then, include the `$redact` stage in the `db.collection.aggregate()` operation to restrict contents of the result set based on the access required to view the data.

For more information on the `$redact` pipeline operator, including its syntax and associated system variables as well as additional examples, see `$redact`.

Procedure

For example, a `forecasts` collection contains documents of the following form where the `tags` field determines the access levels required to view the data:
For each document, the tags field contains various access groupings necessary to view the data. For example, the value `[ [ "G" ], [ "FDW", "TGE" ] ]` can specify that a user requires either access level "G" or both ["FDW", "TGE"].
"FDW", "TGE" ] to view the data.

Consider a user who only has access to view information tagged with either "FDW" or "TGE". To run a query on all documents with year 2014 for this user, include a $redact stage as in the following:

```javascript
var userAccess = [ "FDW", "TGE" ];
db.forecasts.aggregate(
  [
    { $match: { year: 2014 } },
    { $redact: {
      $cond: {
        if: { $anyElementTrue:
          {
            $map: {
              input: "$tags",
              as: "fieldTag",
              in: { $setIsSubset: [ "$fieldTag", userAccess ] }
            }
          },
        then: "$$DESCEND",
        else: "$$PRUNE"
      }
    }
  ]
)
```

The aggregation operation returns the following “redacted” document for the user:

```json
{ "_id" : 1,
  "title" : "123 Department Report",
  "tags" : [ [ "G" ], [ "FDW" ] ],
  "year" : 2014,
  "subsections" : [
    {
      "subtitle" : "Section 1: Overview",
      "tags" : [ [ "SI", "G" ], [ "FDW" ] ],
      "content" : "Section 1: This is the content of section 1."
    },
    {
      "subtitle" : "Section 3: Budgeting",
      "tags" : [ [ "TK" ], [ "FDW", "TGE" ] ]
    }
  ]
}
```

### 3.4 User and Role Management Tutorials

The following tutorials provide instructions on how to enable authentication and limit access for users with privilege roles.
Create a User Administrator (page 67) Create users with special permissions to create, modify, and remove other users, as well as administer authentication credentials (e.g. passwords).

Manage User and Roles (page 69) Manage users by creating new users, creating new roles, and modifying existing users.

Change Your Password and Custom Data (page 75) Users with sufficient access can change their own passwords and modify the optional custom data associated with their user credential.

Create an Administrative User with Unrestricted Access (page 77) Create a user with unrestricted access. Create such a user only in unique situations. In general, all users in the system should have no more access than needed to perform their required operations.

Create a User Administrator

Overview

User administrators create users and create and assigns roles. A user administrator can grant any privilege in the database and can create new ones. In a MongoDB deployment, create the user administrator as the first user. Then let this user create all other users.

To provide user administrators, MongoDB has userAdmin (page 87) and userAdminAnyDatabase (page 92) roles, which grant access to actions (page 99) that support user and role management. Following the policy of least privilege userAdmin (page 87) and userAdminAnyDatabase (page 92) confer no additional privileges.

Carefully control access to these roles. A user with either of these roles can grant itself unlimited additional privileges. Specifically, a user with the userAdmin (page 87) role can grant itself any privilege in the database. A user assigned either the userAdmin (page 87) role on the admin database or the userAdminAnyDatabase (page 92) can grant itself any privilege in the system.

Prerequisites

Required Access

- To create a new user in a database, you must have createUser (page 100) action (page 99) on that database resource (page 98).
- To grant roles to a user, you must have the grantRole (page 100) action (page 99) on the role’s database.

Built-in roles userAdmin (page 87) and userAdminAnyDatabase (page 92) provide createUser (page 100) and grantRole (page 100) actions on their respective resources (page 97).

First User Restrictions If your MongoDB deployment has no users, you must connect to mongod using the localhost exception (page 9) or use the --noauth option when starting mongod to gain full access the system. Once you have access, you can skip to Creating the system user administrator in this procedure.

If users exist in the MongoDB database, but none of them has the appropriate prerequisites to create a new user or you do not have access to them, you must restart mongod with the --noauth option.

Procedure

Step 1: Connect to MongoDB with the appropriate privileges. Connect to mongod or mongos either through the localhost exception (page 9) or as a user with the privileges indicated in the prerequisites section.

In the following example, manager has the required privileges specified in Prerequisites (page 67).
mongo --port 27017 -u manager -p 123456 --authenticationDatabase admin

Step 2: Create the system user administrator. Add the user with the userAdminAnyDatabase (page 92) role, and only that role.

The following example creates the user siteUserAdmin user on the admin database:

```javascript
use admin
db.createUser(
  {
    user: "siteUserAdmin",
    pwd: "password",
    roles: [ { role: "userAdminAnyDatabase", db: "admin" } ]
  }
)
```

Step 3: Create a user administrator for a single database. Optionally, you may want to create user administrators that only have access to administer users in a specific database by way of the userAdmin (page 87) role.

The following example creates the user recordsUserAdmin on the records database:

```javascript
use records
db.createUser(
  {
    user: "recordsUserAdmin",
    pwd: "password",
    roles: [ { role: "userAdmin", db: "records" } ]
  }
)
```

Manage User and Roles

Overview

Changed in version 2.6: MongoDB 2.6 introduces a new authorization model (page 14).

MongoDB employs Role-Based Access Control (RBAC) to determine access for users. A user is granted one or more roles (page 14) that determine the user’s access or privileges to MongoDB resources (page 97) and the actions (page 99) that user can perform. A user should have only the minimal set of privileges required to ensure a system of least privilege.

Each application and user of a MongoDB system should map to a distinct application or administrator. This access isolation facilitates access revocation and ongoing user maintenance.

This tutorial provides examples for user and role management under the MongoDB’s authorization model.

Prerequisites

Important: If you have enabled authorization (page 14) for your deployment, you must authenticate as a user with the required privileges specified in each section. A user administrator (page 67) with the userAdminAnyDatabase (page 92) role, or userAdmin (page 87) role in the specific databases, provides the required privileges to perform the operations listed in this tutorial.

If you have not yet created a user administrator, do so as described in Create a User Administrator (page 67).

Add a User

To create a user, specify the user name, password, and roles (page 14). For users that authenticate using external mechanisms 77, you do not need to provide the password when creating users.

When assigning roles, select the roles that have the exact required privileges (page 14). If the correct roles does not exist, you can create new roles (page 70).

Prerequisites

- To create a new user in a database, you must have createUser (page 100) action (page 99) on that database resource (page 98).
- To grant roles to a user, you must have the grantRole (page 100) action (page 99) on the role’s database.

Built-in roles userAdmin (page 87) and userAdminAnyDatabase (page 92) provide createUser (page 100) and grantRole (page 100) actions on their respective resources (page 97).

Procedure

Step 1: Connect to MongoDB with the appropriate privileges. Connect to mongod or mongos as a user with the privileges specified in the prerequisite section.

The following procedure uses the siteUserAdmin created in Create a User Administrator (page 67).

mongo --port 27017 -u siteUserAdmin -p password --authenticationDatabase admin

77 See x.509 Certificate Authentication (page 8), Kerberos Authentication (page 8), and LDAP Proxy Authority Authentication (page 8)
Step 2: Create the new user. Create the user in the database to which the user will belong. Pass a well formed user document to the `db.createUser()` method.

The following operation creates a user in the `reporting` database with the specified name, password, and roles.

```javascript
use reporting
db.createUser(
  {
    user: "reportsUser",
    pwd: "12345678",
    roles: [
      { role: "read", db: "reporting" },
      { role: "read", db: "products" },
      { role: "read", db: "sales" },
      { role: "readWrite", db: "accounts" }
    ]
  }
)
```

To authenticate the `reportsUser`, you must authenticate the user in the `reporting` database; i.e. specify `--authenticationDatabase reporting`.

You can create a user without assigning roles, choosing instead to assign the roles later. To do so, create the user with an empty `roles` (page 96) array.

Create a User-Defined Role

Roles grant users access to MongoDB resources. MongoDB provides a number of built-in roles (page 85) that administrators can use to control access to a MongoDB system. However, if these roles cannot describe the desired set of privileges, you can create new roles in a particular database.

Except for roles created in the `admin` database, a role can only include privileges that apply to its database and can only inherit from other roles in its database.

A role created in the `admin` database can include privileges that apply to the `admin` database, other databases or to the `cluster` (page 98) resource, and can inherit from roles in other databases as well as the `admin` database.

To create a new role, use the `db.createRole()` method, specifying the privileges in the `privileges` array and the inherited roles in the `roles` array.

MongoDB uses the combination of the database name and the role name to uniquely define a role. Each role is scoped to the database in which you create the role, but MongoDB stores all role information in the `admin.system.roles` collection in the `admin` database.

Prerequisites To create a role in a database, you must have:

- the `createRole` (page 100) action (page 99) on that database resource (page 98).
- the `grantRole` (page 100) action (page 99) on that database to specify privileges for the new role as well as to specify roles to inherit from.

Built-in roles `userAdmin` (page 87) and `userAdminAnyDatabase` (page 92) provide `createRole` (page 100) and `grantRole` (page 100) actions on their respective resources (page 97).

Create a Role to Manage Current Operations The following example creates a role named `manageOpRole` which provides only the privileges to run both `db.currentOp()` and `db.killOp()`.

The built-in role `clusterMonitor` (page 89) also provides the privilege to run `db.currentOp()` along with other privileges, and the built-in role `hostManager` (page 90) provides the privilege to run `db.killOp()` along with other privileges.

---

78 The built-in role `clusterMonitor` (page 89) also provides the privilege to run `db.currentOp()` along with other privileges, and the built-in role `hostManager` (page 90) provides the privilege to run `db.killOp()` along with other privileges.
Step 1: Connect to MongoDB with the appropriate privileges. Connect to `mongod` or `mongos` with the privileges specified in the Prerequisites (page 70) section.

The following procedure uses the `siteUserAdmin` created in Create a User Administrator (page 67).

```bash
mongo --port 27017 -u siteUserAdmin -p password --authenticationDatabase admin
```

The `siteUserAdmin` has privileges to create roles in the `admin` as well as other databases.

Step 2: Create a new role to manage current operations. `manageOpRole` has privileges that act on multiple databases as well as the cluster resource (page 98). As such, you must create the role in the `admin` database.

```javascript
use admin
db.createRole(
    {
        role: "manageOpRole",
        privileges: [
            { resource: { cluster: true }, actions: [ "killOp", "inprog" ] },
            { resource: { db: "", collection: "" }, actions: [ "killCursors" ] }
        ],
        roles: []
    }
)
```

The new role grants permissions to kill any operations.

**Warning:** Terminate running operations with extreme caution. Only use `db.killOp()` to terminate operations initiated by clients and do not terminate internal database operations.

Create a Role to Run `mongostat` The following example creates a role named `mongostatRole` that provides only the privileges to run `mongostat`.  

Step 1: Connect to MongoDB with the appropriate privileges. Connect to `mongod` or `mongos` with the privileges specified in the Prerequisites (page 70) section.

The following procedure uses the `siteUserAdmin` created in Create a User Administrator (page 67).

```bash
mongo --port 27017 -u siteUserAdmin -p password --authenticationDatabase admin
```

The `siteUserAdmin` has privileges to create roles in the `admin` as well as other databases.

Step 2: Create a new role to manage current operations. `mongostatRole` has privileges that act on the cluster resource (page 98). As such, you must create the role in the `admin` database.

```javascript
use admin
db.createRole(
    {
        role: "mongostatRole",
        privileges: [
            { resource: { cluster: true }, actions: [ "serverStatus" ] }
        ],
        roles: []
    }
)
```

The built-in role `clusterMonitor` (page 89) also provides the privilege to run `mongostat` along with other privileges.
Modify Access for Existing User

Prerequisites

- You must have the grantRole (page 100) action (page 99) on a database to grant a role on that database.
- You must have the revokeRole (page 100) action (page 99) on a database to revoke a role on that database.
- To view a role’s information, you must be either explicitly granted the role or must have the viewRole (page 100) action (page 99) on the role’s database.

Procedure

Step 1: Connect to MongoDB with the appropriate privileges. Connect to mongod or mongos as a user with the privileges specified in the prerequisite section.

The following procedure uses the siteUserAdmin created in Create a User Administrator (page 67).

mongo --port 27017 --u siteUserAdmin --p password --authenticationDatabase admin

Step 2: Identify the user’s roles and privileges. To display the roles and privileges of the user to be modified, use the db.getUser() and db.getRole() methods.

For example, to view roles for reportsUser created in Add a User (page 69), issue:

use reporting
db.getUser("reportsUser")

To display the privileges granted to the user by the readWrite role on the "accounts" database, issue:

use accounts
db.getRole( "readWrite", { showPrivileges: true } )

Step 3: Identify the privileges to grant or revoke. If the user requires additional privileges, grant to the user the role, or roles, with the required set of privileges. If such a role does not exist, create a new role (page 70) with the appropriate set of privileges.

To revoke a subset of privileges provided by an existing role: revoke the original role and grant a role that contains only the required privileges. You may need to create a new role (page 70) if a role does not exist.

Step 4: Modify the user’s access.

Revoke a Role Revoke a role with the db.revokeRolesFromUser() method. The following example operation removes the readWrite (page 86) role on the accounts database from the reportsUser:

use reporting
db.revokeRolesFromUser(
  "reportsUser",
  [  
    { role: "readWrite", db: "accounts" }  
  ]
)
Grant a Role  Grant a role using the `db.grantRolesToUser()` method. For example, the following operation grants the `reportsUser` user the `read` (page 85) role on the `accounts` database:

```javascript
use reporting
db.grantRolesToUser(
    "reportsUser",
    [
        { role: "read", db: "accounts" }
    ]
)
```

For sharded clusters, the changes to the user are instant on the mongos on which the command runs. However, for other mongos instances in the cluster, the user cache may wait up to 10 minutes to refresh. See `userCacheInvalidationIntervalSecs`.

Modify Password for Existing User

Prerequisites  To modify the password of another user on a database, you must have the `changeAnyPassword action` (page 99) on that database.

Procedure

Step 1: Connect to MongoDB with the appropriate privileges.  Connect to the mongod or mongos with the privileges specified in the Prerequisites (page 73) section.

The following procedure uses the `siteUserAdmin` created in Create a User Administrator (page 67).

```
mongo --port 27017 -u siteUserAdmin -p password --authenticationDatabase admin
```

Step 2: Change the password. Pass the user's username and the new password to the `db.changeUserPassword()` method.

The following operation changes the `reporting` user's password to `SOh3TbYhxuLiW8ypJPxmt1oOfL`:

```
db.changeUserPassword("reporting", "SOh3TbYhxuLiW8ypJPxmt1oOfL")
```

See also:  Change Your Password and Custom Data (page 75)

View a User's Role

Prerequisites  To view another user's information, you must have the `viewUser` (page 100) action (page 99) on the other user’s database.

Users can view their own information.

Procedure
Step 1: Connect to MongoDB with the appropriate privileges. Connect to mongod or mongos as a user with the privileges specified in the prerequisite section.

The following procedure uses the siteUserAdmin created in Create a User Administrator (page 67).

```
mongo --port 27017 -u siteUserAdmin -p password --authenticationDatabase admin
```

Step 2: Identify the user’s roles. Use the `usersInfo` command or `db.getUser()` method to display user information.

For example, to view roles for reportsUser created in Add a User (page 69), issue:

```javascript
use reporting
db.getUser("reportsUser")
```

In the returned document, the `roles` field displays all roles for reportsUser:

```
...  
"roles" : [  
    { "role" : "readWrite", "db" : "accounts" },  
    { "role" : "read", "db" : "reporting" },  
    { "role" : "read", "db" : "products" },  
    { "role" : "read", "db" : "sales" }

```

View Role’s Privileges

Prerequisites To view a role’s information, you must be either explicitly granted the role or must have the `viewRole` action (page 100) on the role’s database.

Procedure

Step 1: Connect to MongoDB with the appropriate privileges. Connect to mongod or mongos as a user with the privileges specified in the prerequisite section.

The following procedure uses the siteUserAdmin created in Create a User Administrator (page 67).

```
mongo --port 27017 -u siteUserAdmin -p password --authenticationDatabase admin
```

Step 2: Identify the privileges granted by a role. For a given role, use the `db.getRole()` method, or the `rolesInfo` command, with the `showPrivileges` option:

For example, to view the privileges granted by read role on the `products` database, use the following operation, issue:

```
use products
db.getRole("read", { showPrivileges: true })
```

In the returned document, the `privileges` and `inheritedPrivileges` arrays. The `privileges` lists the privileges directly specified by the role and excludes those privileges inherited from other roles. The `inheritedPrivileges` lists all privileges granted by this role, both directly specified and inherited. If the role does not inherit from other roles, the two fields are the same.
"privileges" : [
    {
        "resource": { "db" : "products", "collection" : "" },
        "actions": [ "collStats", "dbHash", "dbStats", "find", "killCursors", "planCacheRead" ]
    },
    {
        "resource": { "db" : "products", "collection" : "system.js" },
        "actions": [ "collStats", "dbHash", "dbStats", "find", "killCursors", "planCacheRead" ]
    }
],
"inheritedPrivileges" : [
    {
        "resource": { "db" : "products", "collection" : "" },
        "actions": [ "collStats", "dbHash", "dbStats", "find", "killCursors", "planCacheRead" ]
    },
    {
        "resource": { "db" : "products", "collection" : "system.js" },
        "actions": [ "collStats", "dbHash", "dbStats", "find", "killCursors", "planCacheRead" ]
    }
]

Change Your Password and Custom Data

Changed in version 2.6.

Overview

Users with appropriate privileges can change their own passwords and custom data. Custom data (page 97) stores optional user information.

Considerations

To generate a strong password for use in this procedure, you can use the openssl utility’s rand command. For example, issue openssl rand with the following options to create a base64-encoded string of 48 pseudo-random bytes:

openssl rand -base64 48

Prerequisites

To modify your own password and custom data, you must have privileges that grant changeOwnPassword (page 99) and changeOwnCustomData (page 99) actions (page 99) respectively on the user’s database.

Step 1: Connect as a user with privileges to manage users and roles. Connect to the mongod or mongos with privileges to manage users and roles, such as a user with userAdminAnyDatabase (page 92) role. The following procedure uses the siteUserAdmin created in Create a User Administrator (page 67).

mongo --port 27017 -u siteUserAdmin -p password --authenticationDatabase admin
Step 2: Create a role with appropriate privileges. In the admin database, create a new role with changeOwnPassword (page 99) and changeOwnCustomData (page 99).

```javascript
use admin
db.createRole(
    { role: "changeOwnPasswordCustomDataRole",
      privileges: [
        {
          resource: { db: "", collection: ""},
          actions: [ "changeOwnPassword", "changeOwnCustomData" ]
        }
      ],
      roles: []
    }
)
```

Step 3: Add a user with this role. In the test database, create a new user with the created "changeOwnPasswordCustomDataRole" role. For example, the following operation creates a user with both the built-in role readWrite (page 86) and the user-created "changeOwnPasswordCustomDataRole".

```javascript
use test
db.createUser(
    { user:"user123",
      pwd:"12345678",
      roles:[ "readWrite", { role:"changeOwnPasswordCustomDataRole", db:"admin" } ]
}
)
```

To grant an existing user the new role, use `db.grantRolesToUser()`.

Procedure

Step 1: Connect with the appropriate privileges. Connect to the mongod or mongos as a user with appropriate privileges.

For example, the following operation connects to MongoDB as user123 created in the Prerequisites (page 75) section.

```
mongo --port 27017 -u user123 -p 12345678 --authenticationDatabase test
```

To check that you have the privileges specified in the Prerequisites (page 75) section as well as to see user information, use the `usersInfo` command with the `showPrivileges` option.

Step 2: Change your password and custom data. Use the `db.updateUser()` method to update the password and custom data.

For example, the following operation changes the user’s password to KN1ZmiaNUp0B and custom data to { title: "Senior Manager" }:

```javascript
use test
db.updateUser(
    "user123",
    { pwd: "KN1ZmiaNUp0B",
      customData: { title: "Senior Manager" }
}
Create an Administrative User with Unrestricted Access

Overview

Most users should have only the minimal set of privileges required for their operations, in keeping with the policy of least privilege. However, some authorization architectures may require a user with unrestricted access. To support these super users, you can create users with access to all database resources (page 97) and actions (page 99).

For many deployments, you may be able to avoid having any users with unrestricted access by having an administrative user with the createUser (page 100) and grantRole (page 100) actions granted as needed to support operations.

If users truly need unrestricted access to a MongoDB deployment, MongoDB provides a built-in role (page 85) named root (page 93) that grants the combined privileges of all built-in roles. This document describes how to create an administrative user with the root (page 93) role.

For descriptions of the access each built-in role provides, see the section on built-in roles (page 85).

Prerequisites

Required Access

- To create a new user in a database, you must have createUser (page 100) action (page 99) on that database resource (page 98).
- To grant roles to a user, you must have the grantRole (page 100) action (page 99) on the role’s database.

Built-in roles userAdmin (page 87) and userAdminAnyDatabase (page 92) provide createUser (page 100) and grantRole (page 100) actions on their respective resources (page 97).

First User Restrictions  If your MongoDB deployment has no users, you must connect to mongod using the local-host exception (page 9) or use the --noauth option when starting mongod to gain full access the system. Once you have access, you can skip to Creating the system user administrator in this procedure.

If users exist in the MongoDB database, but none of them has the appropriate prerequisites to create a new user or you do not have access to them, you must restart mongod with the --noauth option.

Procedure

Step 1: Connect to MongoDB with the appropriate privileges.  Connect to the mongod or mongos as a user with the privileges specified in the Prerequisites (page 77) section.

The following procedure uses the siteUserAdmin created in Create a User Administrator (page 67).

mongo --port 27017 -u siteUserAdmin -p password --authenticationDatabase admin

Step 2: Create the administrative user.  In the admin database, create a new user using the db.createUser() method. Give the user the built-in root (page 93) role.

For example:
use admin

db.createUser(
    {
        user: "superuser",
        pwd: "12345678",
        roles: [ "root" ]
    }
)
)

Authenticate against the admin database to test the new user account. Use db.auth() while using the admin
database or use the mongo shell with the --authenticationDatabase option.

### 3.5 Auditing Tutorials

The following tutorials provide instructions on how to enable auditing for system events and specify which events to
audit.

**Configure System Events Auditing** *(page 78)* Enable and configure MongoDB Enterprise system event auditing fea-
ture.

**Configure Audit Filters** *(page 80)* Specify which events to audit.

### Configure System Events Auditing

New in version 2.6.

**MongoDB Enterprise**[^80] supports auditing *(page 16)* of various operations. A complete auditing solution must involve all mongod server and mongos router processes.

The audit facility can write audit events to the console, the syslog (option is unavailable on Windows), a JSON file,
or a BSON file. For details on the audited operations and the audit log messages, see *System Event Audit Messages*
*(page 104)*.

### Enable and Configure Audit Output

Use the --auditDestination option to enable auditing and specify where to output the audit events.

**Warning:** For sharded clusters, if you enable auditing on mongos instances, you must enable auditing on all
mongod instances in the cluster, i.e. shards and config servers.

**Output to Syslog**  To enable auditing and print audit events to the syslog (option is unavailable on Windows) in
JSON format, specify syslog for the --auditDestination setting. For example:

```
mongod --dbpath data/db --auditDestination syslog
```

**Warning:** The syslog message limit can result in the truncation of the audit messages. The auditing system will
neither detect the truncation nor error upon its occurrence.

You may also specify these options in the *configuration file*:

[^80]: https://www.mongodb.com/products/mongodb-enterprise-advanced?jmp=docs
Storage:
    dbPath: data/db
auditLog:
    destination: syslog

Output to Console  To enable auditing and print the audit events to standard output (i.e. stdout), specify console for the --auditDestination setting. For example:

mongod --dbpath data/db --auditDestination console

You may also specify these options in the configuration file:

storage:
    dbPath: data/db
auditLog:
    destination: console

Output to JSON File  To enable auditing and print audit events to a file in JSON format, specify file for the --auditDestination setting, JSON for the --auditFormat setting, and the output filename for the --auditPath. The --auditPath option accepts either full path name or relative path name. For example, the following enables auditing and records audit events to a file with the relative path name of data/db/auditLog.json:

mongod --dbpath data/db --auditDestination file --auditFormat JSON --auditPath data/db/auditLog.json

The audit file rotates at the same time as the server log file.

You may also specify these options in the configuration file:

storage:
    dbPath: data/db
auditLog:
    destination: file
    format: JSON
    path: data/db/auditLog.json

Note:  Printing audit events to a file in JSON format degrades server performance more than printing to a file in BSON format.

Output to BSON File  To enable auditing and print audit events to a file in BSON binary format, specify file for the --auditDestination setting, BSON for the --auditFormat setting, and the output filename for the --auditPath. The --auditPath option accepts either full path name or relative path name. For example, the following enables auditing and records audit events to a BSON file with the relative path name of data/db/auditLog.bson:

mongod --dbpath data/db --auditDestination file --auditFormat BSON --auditPath data/db/auditLog.bson

The audit file rotates at the same time as the server log file.

You may also specify these options in the configuration file:

storage:
    dbPath: data/db
auditLog:
    destination: file
To view the contents of the file, pass the file to the MongoDB utility `bsondump`. For example, the following converts the audit log into a human-readable form and output to the terminal:

`bsondump data/db/auditLog.bson`

**See also:**

Configure Audit Filters (page 80), Auditing (page 16), System Event Audit Messages (page 104)

**Configure Audit Filters**

MongoDB Enterprise supports auditing (page 16) of various operations. When enabled (page 78), the audit facility, by default, records all auditable operations as detailed in Audit Event Actions, Details, and Results (page 105). To specify which events to record, the audit feature includes the `--auditFilter` option.

**--auditFilter Option**

The `--auditFilter` option takes a string representation of a query document of the form:

```
{ <field1>: <expression1>, ... }  
```

- The `<field>` can be any field in the audit message (page 104), including fields returned in the `param` (page 105) document.
- The `<expression>` is a query condition expression.

To specify an audit filter, enclose the filter document in single quotes to pass the document as a string.
To specify the audit filter in a configuration file, you must use the YAML format of the configuration file.

**Examples**

**Filter for Multiple Operation Types**  The following example audits only the `createCollection` (page 99) and `dropCollection` (page 100) actions by using the filter:

```
{ atype: { $in: [ "createCollection", "dropCollection" ] } }
```

To specify an audit filter, enclose the filter document in single quotes to pass the document as a string.

```
mongod --dbpath data/db --auditDestination file --auditFilter '{ atype: { $in: [ "createCollection", "dropCollection" ] } }'
```

To specify the audit filter in a configuration file, you must use the YAML format of the configuration file.

```yaml
storage:
  dbPath: data/db
auditLog:
  destination: file
  format: BSON
  path: data/db/auditLog.bson
  filter: '{ atype: { $in: [ "createCollection", "dropCollection" ] } }'
```

---

81https://www.mongodb.com/products/mongodb-enterprise-advanced?jmp=docs
**Filter on Authentication Operations on a Single Database**  
The `<field>` can include any field in the audit message (page 104). For authentication operations (i.e. `atype: "authenticate"`), the audit messages include a `db` field in the `param` document.

The following example audits only the `authenticate` operations that occur against the `test` database by using the filter:  
```javascript
{ atype: "authenticate", "param.db": "test" }
```

To specify an audit filter, enclose the filter document in single quotes to pass the document as a string.

`mongod --dbpath data/db --auth --auditDestination file --auditFilter '{ atype: "authenticate", "param.db": "test" }' --auditFormat BSON --auditPath data/db/auditLog.bson`

To specify the audit filter in a configuration file, you must use the YAML format of the configuration file.

```
storage:
  dbPath: data/db
security:
  authorization: enabled
auditLog:
  destination: file
  format: BSON
  path: data/db/auditLog.bson
  filter: '{ atype: "authenticate", "param.db": "test" }'
```

To filter on all `authenticate` operations across databases, use the filter `{ atype: "authenticate" }`.

**Filter on Collection Creation and Drop Operations for a Single Database**  
The `<field>` can include any field in the audit message (page 104). For collection creation and drop operations (i.e. `atype: "createCollection"` and `atype: "dropCollection"`), the audit messages include a namespace `ns` field in the `param` document.

The following example audits only the `createCollection` and `dropCollection` operations that occur against the `test` database by using the filter:

```javascript
{ atype: { $in: [ "createCollection", "dropCollection" ] }, "param.ns": /^test\./ }
```

To specify an audit filter, enclose the filter document in single quotes to pass the document as a string.

`mongod --dbpath data/db --auth --auditDestination file --auditFilter '{ atype: { $in: [ "createCollection", "dropCollection" ] }, "param.ns": /^test\./ }' --auditFormat BSON --auditPath data/db/auditLog.bson`

To specify the audit filter in a configuration file, you must use the YAML format of the configuration file.

```
storage:
  dbPath: data/db
security:
  authorization: enabled
auditLog:
  destination: file
  format: BSON
  path: data/db/auditLog.bson
  filter: '{ atype: { $in: [ "createCollection", "dropCollection" ] }, "param.ns": /^test\./ }'
```

**Filter by Authorization Role**  
The following example audits operations by users with `readWrite` (page 86) role on the `test` database, including users with roles that inherit from `readWrite` (page 86), by using the filter:

```javascript
{ atype: { $in: [ "createCollection", "dropCollection" ] }, "param.ns": /^test\./ }
```

To specify an audit filter, enclose the filter document in single quotes to pass the document as a string.

`mongod --dbpath data/db --auth --auditDestination file --auditFilter '{ atype: { $in: [ "createCollection", "dropCollection" ] }, "param.ns": /^test\./ }' --auditFormat BSON --auditPath data/db/auditLog.bson`

To specify the audit filter in a configuration file, you must use the YAML format of the configuration file.

```
storage:
  dbPath: data/db
security:
  authorization: enabled
auditLog:
  destination: file
  format: BSON
  path: data/db/auditLog.bson
  filter: '{ atype: { $in: [ "createCollection", "dropCollection" ] }, "param.ns": /^test\./ }'
```
To specify an audit filter, enclose the filter document in single quotes to pass the document as a string.

```
mongod --dbpath data/db --auth --auditDestination file --auditFilter '{ roles: { role: "readWrite", db: "test" } }' --auditFormat BSON --auditPath data/db/auditLog.bson
```

To specify the audit filter in a configuration file, you must use the YAML format of the configuration file.

```
storage:
  dbPath: data/db
security:
  authorization: enabled
auditLog:
  destination: file
  format: BSON
  path: data/db/auditLog.bson
  filter: '{ roles: { role: "readWrite", db: "test" } }'
```

Filter on Read and Write Operations

To capture read and write operations in the audit, you must also enable the audit system to log authorization successes using the `auditAuthorizationSuccess` parameter.

**Note:** Enabling `auditAuthorizationSuccess` degrades performance more than logging only the authorization failures.

The following example audits the `find()`, `insert()`, `remove()`, `update()`, `save()`, and `findAndModify()` operations by using the filter:

```
{ atype: "authCheck", "param.command": { $in: [ "find", "insert", "delete", "update", "findandmodify" ] } }
```

To specify an audit filter, enclose the filter document in single quotes to pass the document as a string.

```
mongod --dbpath data/db --auth --setParameter auditAuthorizationSuccess=true --auditDestination file --auditFilter '{ atype: "authCheck", "param.command": { $in: [ "find", "insert", "delete", "update", "findandmodify" ] } }' --auditFormat BSON --auditPath data/db/auditLog.bson
```

To specify the audit filter in a configuration file, you must use the YAML format of the configuration file.

```
storage:
  dbPath: data/db
security:
  authorization: enabled
auditLog:
  destination: file
  format: BSON
  path: data/db/auditLog.bson
  filter: '{ atype: "authCheck", "param.command": { $in: [ "find", "insert", "delete", "update", "findandmodify" ] } }
  setParameter: { auditAuthorizationSuccess: true }
```

Filter on Read and Write Operations for a Collection

To capture read and write operations in the audit, you must also enable the audit system to log authorization successes using the `auditAuthorizationSuccess` parameter.

**Note:** Enabling `auditAuthorizationSuccess` degrades performance more than logging only the authorization failures.

---

---

82 You can enable `auditAuthorizationSuccess` parameter without enabling `--auth`; however, all operations will return success for authorization checks.
The following example audits the \texttt{find()}, \texttt{insert()}, \texttt{remove()}, \texttt{update()}, and \texttt{findAndModify()} operations for the collection \texttt{orders} in the database \texttt{test} by using the filter:

\begin{verbatim}
{ atype: "authCheck", "param.ns": "test.orders", "param.command": { $in: [ "find", "insert", "delete", "update", "findandmodify" ] } }
\end{verbatim}

To specify an audit filter, enclose the filter document in single quotes to pass the document as a string.

```
mongod --dbpath data/db --auth --setParameter auditAuthorizationSuccess=true --auditDestination file
```

To specify the audit filter in a \texttt{configuration} file, you must use the YAML format of the configuration file.

```
storage:
dbPath: data/db
security:
  authorization: enabled
auditLog:
  destination: file
  format: BSON
  path: data/db/auditLog.bson
  filter: '{ atype: "authCheck", "param.ns": "test.orders", "param.command": { $in: [ "find", "insert", "delete", "update", "findandmodify" ] } }'
  setParameter: { auditAuthorizationSuccess: true }
```

### 3.6 Create a Vulnerability Report

If you believe you have discovered a vulnerability in MongoDB or have experienced a security incident related to MongoDB, please report the issue to aid in its resolution.

To report an issue, we strongly suggest filing a ticket in the \texttt{SECURITY}\textsuperscript{83} project in JIRA. MongoDB, Inc responds to vulnerability notifications within 48 hours.

#### Create the Report in JIRA

Submit a Ticket\textsuperscript{84} in the Security\textsuperscript{85} project on our JIRA. The ticket number will become the reference identification for the issue for its lifetime. You can use this identifier for tracking purposes.

#### Information to Provide

All vulnerability reports should contain as much information as possible so MongoDB’s developers can move quickly to resolve the issue. In particular, please include the following:

- The name of the product.
- \textit{Common Vulnerability} information, if applicable, including:
  - CVSS (Common Vulnerability Scoring System) Score.
  - CVE (Common Vulnerability and Exposures) Identifier.
- Contact information, including an email address and/or phone number, if applicable.

\textsuperscript{83}https://jira.mongodb.org/browse/SECURITY
\textsuperscript{84}https://jira.mongodb.org/secure/CreateIssue default.jspa?project-field=%22Security%22
\textsuperscript{85}https://jira.mongodb.org/browse/SECURITY
Send the Report via Email

While JIRA is the preferred reporting method, you may also report vulnerabilities via email to security@mongodb.com. You may encrypt email using MongoDB’s public key at https://docs.mongodb.org/10gen-security-gpg-key.asc. MongoDB, Inc. responds to vulnerability reports sent via email with a response email that contains a reference number for a JIRA ticket posted to the SECURITY project.

Evaluation of a Vulnerability Report

MongoDB, Inc. validates all submitted vulnerabilities and uses Jira to track all communications regarding a vulnerability, including requests for clarification or additional information. If needed, MongoDB representatives set up a conference call to exchange information regarding the vulnerability.

Disclosure

MongoDB, Inc. requests that you do not publicly disclose any information regarding the vulnerability or exploit the issue until it has had the opportunity to analyze the vulnerability, to respond to the notification, and to notify key users, customers, and partners.

The amount of time required to validate a reported vulnerability depends on the complexity and severity of the issue. MongoDB, Inc. takes all required vulnerabilities very seriously and will always ensure that there is a clear and open channel of communication with the reporter.

After validating an issue, MongoDB, Inc. coordinates public disclosure of the issue with the reporter in a mutually agreed timeframe and format. If required or requested, the reporter of a vulnerability will receive credit in the published security bulletin.

4.2 Security Reference Documentation

**Built-In Roles** (page 85) Reference on MongoDB provided roles and corresponding access.

**system.roles Collection** (page 93) Describes the content of the collection that stores user-defined roles.

**system.users Collection** (page 96) Describes the content of the collection that stores users’ credentials and role assignments.

**Resource Document** (page 97) Describes the resource document for roles.

**Privilege Actions** (page 99) List of the actions available for privileges.

**Default MongoDB Port** (page 104) List of default ports used by MongoDB.

**System Event Audit Messages** (page 104) Reference on system event audit messages.

**Built-In Roles**

MongoDB grants access to data and commands through role-based authorization (page 14) and provides built-in roles that provide the different levels of access commonly needed in a database system. You can additionally create user-defined roles (page 15).

A role grants privileges to perform sets of actions (page 99) on defined resources (page 97). A given role applies to the database on which it is defined and can grant access down to a collection level of granularity.

Each of MongoDB’s built-in roles defines access at the database level for all non-system collections in the role’s database and at the collection level for all system collections.

MongoDB provides the built-in database user (page 85) and database administration (page 86) roles on every database. MongoDB provides all other built-in roles only on the admin database.

This section describes the privileges for each built-in role. You can also view the privileges for a built-in role at any time by issuing the rolesInfo command with the showPrivileges and showBuiltInRoles fields both set to true.

**Database User Roles**

Every database includes the following client roles:

**read**

Provides the ability to read data on all non-system collections and on the following system collections:
system.indexes, system.js, and system.namespaces collections. The role provides read access by granting the following actions (page 99):

- `collStats` (page 103)
- `dbHash` (page 103)
- `dbStats` (page 103)
- `find` (page 99)
- `killCursors` (page 100)
- `listIndexes` (page 103)
- `listCollections` (page 103)

**readWrite**

Provides all the privileges of the read (page 85) role plus ability to modify data on all non-system collections and the system.js collection. The role provides the following actions on those collections:

- `collStats` (page 103)
- `convertToCapped` (page 102)
- `createCollection` (page 99)
- `dbHash` (page 103)
- `dbStats` (page 103)
- `dropCollection` (page 100)
- `createIndex` (page 99)
- `dropIndex` (page 102)
- `emptycapped` (page 100)
- `find` (page 99)
- `insert` (page 99)
- `killCursors` (page 100)
- `listIndexes` (page 103)
- `listCollections` (page 103)
- `remove` (page 99)
- `renameCollectionSameDB` (page 102)
- `update` (page 99)

**Database Administration Roles**

Every database includes the following database administration roles:

**dbAdmin**

Provides the following actions (page 99) on the database’s system.indexes, system.namespaces, and system.profile collections:

- `collStats` (page 103)
- `dbHash` (page 103)
• **dbStats** (page 103)
• **find** (page 99)
• **killCursors** (page 100)
• **listIndexes** (page 103)
• **listCollections** (page 103)
• **dropCollection** (page 100) and **createCollection** (page 99) on system.profile only

Changed in version 2.6.4: **dbAdmin** (page 86) added the **createCollection** (page 99) for the system.profile collection. Previous versions only had the **dropCollection** (page 100) on the system.profile collection.

Provides the following actions on all non-system collections. This role does not include full read access on non-system collections:

• **collMod** (page 102)
• **collStats** (page 103)
• **compact** (page 102)
• **convertToCapped** (page 102)
• **createCollection** (page 99)
• **createIndex** (page 99)
• **dbStats** (page 103)
• **dropCollection** (page 100)
• **dropDatabase** (page 102)
• **dropIndex** (page 102)
• **enableProfiler** (page 100)
• **indexStats** (page 103)
• **reIndex** (page 102)
• **renameCollectionSameDB** (page 102)
• **repairDatabase** (page 103)
• **storageDetails** (page 101)
• **validate** (page 103)

**dbOwner**

The database owner can perform any administrative action on the database. This role combines the privileges granted by the **readWrite** (page 86), **dbAdmin** (page 86) and **userAdmin** (page 87) roles.

**userAdmin**

Provides the ability to create and modify roles and users on the current database. This role also indirectly provides **superuser** (page 92) access to either the database or, if scoped to the admin database, the cluster. The **userAdmin** (page 87) role allows users to grant any user any privilege, including themselves.

The **userAdmin** (page 87) role explicitly provides the following actions:

• **changeCustomData** (page 99)
• **changePassword** (page 99)
• **createRole** (page 100)
Cluster Administration Roles

The admin database includes the following roles for administering the whole system rather than just a single database. These roles include but are not limited to replica set and sharded cluster administrative functions.

**clusterAdmin**
Provides the greatest cluster-management access. This role combines the privileges granted by the clusterManager (page 88), clusterMonitor (page 89), and hostManager (page 90) roles. Additionally, the role provides the dropDatabase (page 102) action.

**clusterManager**
Provides management and monitoring actions on the cluster. A user with this role can access the config and local databases, which are used in sharding and replication, respectively.

Provides the following actions on the cluster as a whole:

- addShard (page 101)
- applicationMessage (page 102)
- cleanupOrphaned (page 100)
- flushRouterConfig (page 101)
- listShards (page 101)
- removeShard (page 102)
- replSetConfigure (page 101)
- replSetGetStatus (page 101)
- replSetStateChange (page 101)
- resync (page 101)

Provides the following actions on all databases in the cluster:

- enableSharding (page 101)
- moveChunk (page 101)
- splitChunk (page 102)
- splitVector (page 102)

On the config database, provides the following actions on the settings collection:

- insert (page 99)
- remove (page 99)
- update (page 99)
On the config database, provides the following actions on all configuration collections and on the system.indexes, system.js, and system.namespaces collections:

- `collStats` (page 103)
- `dbHash` (page 103)
- `dbStats` (page 103)
- `find` (page 99)
- `killCursors` (page 100)

On the local database, provides the following actions on the replset collection:

- `collStats` (page 103)
- `dbHash` (page 103)
- `dbStats` (page 103)
- `find` (page 99)
- `killCursors` (page 100)

**clusterMonitor**
Provides read-only access to monitoring tools, such as the MongoDB Cloud Manager\(^\text{88}\) and Ops Manager\(^\text{89}\) monitoring agent.

Provides the following actions on the cluster as a whole:

- `connPoolStats` (page 103)
- `cursorInfo` (page 103)
- `getCmdLineOpts` (page 103)
- `getLog` (page 103)
- `getParameter` (page 102)
- `getShardMap` (page 101)
- `hostInfo` (page 102)
- `inprog` (page 100)
- `listDatabases` (page 103)
- `listShards` (page 101)
- `netstat` (page 103)
- `replSetGetStatus` (page 101)
- `serverStatus` (page 103)
- `shardingState` (page 102)
- `top` (page 104)

Provides the following actions on all databases in the cluster:

- `collStats` (page 103)
- `dbStats` (page 103)
- `getShardVersion` (page 101)

\(^\text{88}\)https://cloud.mongodb.com/?jmp=docs
\(^\text{89}\)https://docs.opsmanager.mongodb.com/current/
Provides the **find** (page 99) action on all **system.profile** collections in the cluster.

Provides the following actions on the **config** database’s configuration collections and **system.indexes**, **system.js**, and **system.namespaces** collections:

- **collStats** (page 103)
- **dbHash** (page 103)
- **dbStats** (page 103)
- **find** (page 99)
- **killCursors** (page 100)

**hostManager**

Provides the ability to monitor and manage servers.

Provides the following actions on the cluster as a whole:

- **applicationMessage** (page 102)
- **closeAllDatabases** (page 102)
- **connPoolSync** (page 102)
- **cpuProfiler** (page 100)
- **diagLogging** (page 103)
- **flushRouterConfig** (page 101)
- **fsync** (page 102)
- **invalidateUserCache** (page 100)
- **killOp** (page 101)
- **logRotate** (page 102)
- **resync** (page 101)
- **setParameter** (page 103)
- **shutdown** (page 103)
- **touch** (page 103)
- **unlock** (page 100)

Provides the following actions on all databases in the cluster:

- **killCursors** (page 100)
- **repairDatabase** (page 103)

**Backup and Restoration Roles**

The **admin** database includes the following roles for backing up and restoring data:

**backup**

Provides minimal privileges needed for backing up data. This role provides sufficient privileges to use the **MongoDB Cloud Manager** backup agent, **Ops Manager** backup agent, or to use **mongodump** to back up an entire **mongod** instance.

---

90 https://cloud.mongodb.com/? jmp=docs
91 https://docs.opsmanager.mongodb.com/current/
Provides the following actions (page 99) on the mms.backup collection in the admin database:

- **insert** (page 99)
- **update** (page 99)

Provides the listDatabases (page 103) action on the cluster as a whole.

Provides the listCollections (page 103) action on all databases.

Provides the listIndexes (page 103) action for all collections.

Provides the find (page 99) action on the following:

- all non-system collections in the cluster
- all the following system collections in the cluster: system.indexes, system.namespaces, and system.js
- the admin.system.users and admin.system.roles collections
- legacy system.users collections from versions of MongoDB prior to 2.6

To back up the system.profile collection, which is created when you activate database profiling, you must have additional read access on this collection. Several roles provide this access, including the clusterAdmin (page 88) and dbAdmin (page 86) roles.

**restore**

Provides minimal privileges needed for restoring data from backups. This role provides sufficient privileges to use the mongorestore tool to restore an entire mongod instance.

Provides the following actions on all non-system collections and system.js collections in the cluster; on the admin.system.users and admin.system.roles collections in the admin database; and on legacy system.users collections from versions of MongoDB prior to 2.6:

- **collMod** (page 102)
- **createCollection** (page 99)
- **createIndex** (page 99)
- **dropCollection** (page 100)
- **insert** (page 99)

Provides the listCollections (page 103) action on all databases.

Provides the following additional actions on admin.system.users and legacy system.users collections:

- **find** (page 99)
- **remove** (page 99)
- **update** (page 99)

Provides the find (page 99) action on all the system.namespaces collections in the cluster.

Although, restore (page 91) includes the ability to modify the documents in the admin.system.users collection using normal modification operations, only modify these data using the user management methods.

**All-Database Roles**

The admin database provides the following roles that apply to all databases in a mongod instance and are roughly equivalent to their single-database equivalents:
**readAnyDatabase**
Provides the same read-only permissions as **read** (page 85), except it applies to all databases in the cluster. The role also provides the **listDatabases** (page 103) action on the cluster as a whole.

**readWriteAnyDatabase**
Provides the same read and write permissions as **readWrite** (page 86), except it applies to all databases in the cluster. The role also provides the **listDatabases** (page 103) action on the cluster as a whole.

**userAdminAnyDatabase**
Provides the same access to user administration operations as **userAdmin** (page 87), except it applies to all databases in the cluster. The role also provides the following actions on the cluster as a whole:
- **authSchemaUpgrade** (page 100)
- **invalidateUserCache** (page 100)
- **listDatabases** (page 103)

The role also provides the following actions on the **admin.system.users** and **admin.system.roles** collections on the **admin** database, and on legacy **system.users** collections from versions of MongoDB prior to 2.6:
- **collStats** (page 103)
- **dbHash** (page 103)
- **dbStats** (page 103)
- **find** (page 99)
- **killCursors** (page 100)
- **planCacheRead** (page 101)

Changed in version 2.6.4: **userAdminAnyDatabase** (page 92) added the following permissions on the **admin.system.users** and **admin.system.roles** collections:
- **createIndex** (page 99)
- **dropIndex** (page 102)

The **userAdminAnyDatabase** (page 92) role does not restrict the permissions that a user can grant. As a result, **userAdminAnyDatabase** (page 92) users can grant themselves privileges in excess of their current privileges and even can grant themselves all privileges, even though the role does not explicitly authorize privileges beyond user administration. This role is effectively a MongoDB system **superuser** (page 92).

**dbAdminAnyDatabase**
Provides the same access to database administration operations as **dbAdmin** (page 86), except it applies to all databases in the cluster. The role also provides the **listDatabases** (page 103) action on the cluster as a whole.

**Superuser Roles**

Several roles provide either indirect or direct system-wide superuser access.

The following roles provide the ability to assign any user any privilege on any database, which means that users with one of these roles can assign themselves any privilege on any database:
- **dBOwner** (page 87) role, when scoped to the **admin** database
- **userAdmin** (page 87) role, when scoped to the **admin** database
- **userAdminAnyDatabase** (page 92) role
The following role provides full privileges on all resources:

**root**

Provides access to the operations and all the resources of the `readWriteAnyDatabase` (page 92), `dbAdminAnyDatabase` (page 92), `userAdminAnyDatabase` (page 92) and `clusterAdmin` (page 88) roles combined.

`root` does not include any access to collections that begin with the `system` prefix.

For example, without the ability to insert data directly into the: `data.system.users <admin.system.users>` and `system.roles` collections in the `admin` database. `root` is not suitable for writing or restoring data that have these collections (e.g. with `mongorestore`. To perform these kinds of restore operations, provision users with the `restore` (page 91) role.

**Internal Role**

__system__

MongoDB assigns this role to user objects that represent cluster members, such as replica set members and `mongos` instances. The role entitles its holder to take any action against any object in the database.

Do not assign this role to user objects representing applications or human administrators, other than in exceptional circumstances.

If you need access to all actions on all resources, for example to run `applyOps` commands, do not assign this role. Instead, create a user-defined role (page 70) that grants `anyAction` (page 104) on `anyResource` (page 99) and ensure that only the users who need access to these operations have this access.

**system.roles Collection**

New in version 2.6.

The `system.roles` collection in the `admin` database stores the user-defined roles. To create and manage these user-defined roles, MongoDB provides role management commands.

**system.roles Schema**

The documents in the `system.roles` collection have the following schema:

```json
{
  _id: <system-defined id>,
  role: "<role name>",
  db: "<database>",
  privileges:
    [
      {
        resource: { <resource> },
        actions: [ "<action>", ... ]
      },
      ...
    ],
  roles:
    [
      { role: "<role name>", db: "<database>" },
      ...
    ]
}
```
A `system.roles` document has the following fields:

**admin.system.roles.role**

The `role` field is a string that specifies the name of the role.

**admin.system.roles.db**

The `db` field is a string that specifies the database to which the role belongs. MongoDB uniquely identifies each role by the pairing of its name (i.e. `role`) and its database.

**admin.system.roles.privileges**

The `privileges` array contains the privilege documents that define the privileges for the role.

A privilege document has the following syntax:

```
{
  resource: { <resource> },
  actions: [ "<action>", ... ]
}
```

Each privilege document has the following fields:

**admin.system.roles.privileges[n].resource**

A document that specifies the resources upon which the privilege actions apply. The document has one of the following form:

```
{ db: <database>, collection: <collection> }
```

or

```
{ cluster: true }
```

See *Resource Document* for more details.

**admin.system.roles.privileges[n].actions**

An array of actions permitted on the resource. For a list of actions, see *Privilege Actions*.

**admin.system.roles.roles**

The `roles` array contains role documents that specify the roles from which this role inherits privileges.

A role document has the following syntax:

```
{ role: "<role name>", db: "<database>" }
```

A role document has the following fields:

**admin.system.roles.roles[n].role**

The name of the role. A role can be a built-in role provided by MongoDB or a user-defined role.

**admin.system.roles.roles[n].db**

The name of the database where the role is defined.

**Examples**

Consider the following sample documents found in `system.roles` collection of the `admin` database.
A User-Defined Role Specifies Privileges  The following is a sample document for a user-defined role `appUser` defined for the `myApp` database:

```javascript
{
  _id: "myApp.appUser",
  role: "appUser",
  db: "myApp",
  privileges: [
    {
      resource: { db: "myApp", collection: "" },
      actions: [ "find", "createCollection", "dbStats", "collStats" ] },
    {
      resource: { db: "myApp", collection: "logs" },
      actions: [ "insert" ] },
    {
      resource: { db: "myApp", collection: "data" },
      actions: [ "insert", "update", "remove", "compact" ] },
    {
      resource: { db: "myApp", collection: "system.js" },
      actions: [ "find" ] },
  ],
  roles: []
}
```

The `privileges` array lists the five privileges that the `appUser` role specifies:

- The first privilege permits its actions ("find", "createCollection", "dbStats", "collStats") on all the collections in the `myApp` database `excluding` its system collections. See Specify a Database as Resource (page 98).
- The next two privileges permits additional actions on specific collections, `logs` and `data`, in the `myApp` database. See Specify a Collection of a Database as Resource (page 97).
- The last privilege permits actions on one `system collections` in the `myApp` database. While the first privilege gives database-wide permission for the `find` action, the action does not apply to `myApp`’s system collections. To give access to a system collection, a privilege must explicitly specify the collection. See Resource Document (page 97).

As indicated by the empty `roles` array, `appUser` inherits no additional privileges from other roles.

User-Defined Role Inherits from Other Roles  The following is a sample document for a user-defined role `appAdmin` defined for the `myApp` database: The document shows that the `appAdmin` role specifies privileges as well as inherits privileges from other roles:

```javascript
{
  _id: "myApp.appAdmin",
  role: "appAdmin",
  db: "myApp",
  privileges: [
    {
      resource: { db: "myApp", collection: "" },
      actions: [ "insert", "dbStats", "collStats", "compact", "repairDatabase" ]
    },
    {
      role: "appUser",
      db: "myApp"
    }
  ],
  roles: []
}
```

The `privileges` array lists the privileges that the `appAdmin` role specifies. This role has a single privilege that permits its actions ("insert", "dbStats", "collStats", "compact", "repairDatabase") on all the collections in the `myApp` database `excluding` its system collections. See Specify a Database as Resource (page 98).
The roles array lists the roles, identified by the role names and databases, from which the role appAdmin inherits privileges.

**system.users Collection**

Changed in version 2.6.

The system.users collection in the admin database stores user authentication (page 6) and authorization (page 14) information. To manage data in this collection, MongoDB provides user management commands.

**system.users Schema**

The documents in the system.users collection have the following schema:

```json
{
  _id: <system defined id>,
  user: "<name>",
  db: "<database>",
  credentials: { <authentication credentials> },
  roles: [
    { role: "<role name>", db: "<database>" },
    ...
  ],
  customData: <custom information>
}
```

Each system.users document has the following fields:

**admin.system.users.user**

The user (page 96) field is a string that identifies the user. A user exists in the context of a single logical database but can have access to other databases through roles specified in the roles (page 96) array.

**admin.system.users.db**

The db (page 96) field specifies the database associated with the user. The user’s privileges are not necessarily limited to this database. The user can have privileges in additional databases through the roles (page 96) array.

**admin.system.users.credentials**

The credentials (page 96) field contains the user’s authentication information. For users with externally stored authentication credentials, such as users that use Kerberos (page 55) or x.509 certificates for authentication, the system.users document for that user does not contain the credentials (page 96) field.

**admin.system.users.roles**

The roles (page 96) array contains role documents that specify the roles granted to the user. The array contains both built-in roles (page 85) and user-defined role (page 15).

A role document has the following syntax:

```json
{ role: "<role name>", db: "<database>" }
```

A role document has the following fields:

**admin.system.users.roles[n].role**

The name of a role. A role can be a built-in role (page 85) provided by MongoDB or a custom user-defined role (page 15).

**admin.system.users.roles[n].db**

The name of the database where role is defined.
When specifying a role using the role management or user management commands, you can specify the role name alone (e.g. "readWrite") if the role that exists on the database on which the command is run.

```
admin.system.users.customData
```

The customData (page 97) field contains optional custom information about the user.

**Example**

Changed in version 3.0.0.

Consider the following document in the system.users collection:

```
{
  _id : "home.Kari",
  user : "Kari",
  db : "home",
  credentials : {
    "SCRAM-SHA-1" : {
      "iterationCount" : 10000,
      "salt" : "nkHYXEZTTYmn+hrY994y1Q==",
      "storedKey" : "wxWGN3E1Q25WbPjAcExdUmN4nNo==",
      "serverKey" : "h7vBq5tACT/BtrIE1Y2QTm+pQzM="
    }
  },
  roles : [
    { role: "read", db: "home" },
    { role: "readWrite", db: "test" },
    { role: "appUser", db: "myApp" }
  ],
  customData : { zipCode: "64157" }
}
```

The document shows that a user Kari is associated with the home database. Kari has the read (page 85) role in the home database, the readWrite (page 86) role in the test database, and the appUser role in the myApp database.

**Resource Document**

The resource document specifies the resources upon which a privilege permits actions.

**Database and/or Collection Resource**

To specify databases and/or collections, use the following syntax:

```
{ db: <database>, collection: <collection> }
```

**Specify a Collection of a Database as Resource**  If the resource document specifies both the db and collection fields as non-empty strings, the resource is the specified collection in the specified database. For example, the following document specifies a resource of the inventory collection in the products database:

```
{ db: "products", collection: "inventory" }
```

For a user-defined role scoped for a non-admin database, the resource specification for its privileges must specify the same database as the role. User-defined roles scoped for the admin database can specify other databases.
Specify a Database as Resource  If only the `collection` field is an empty string (""), the resource is the specified database, excluding the system collections. For example, the following resource document specifies the resource of the `test` database, excluding the system collections:

```
{ db: "test", collection: "" }
```

For a user-defined role scoped for a non-admin database, the resource specification for its privileges must specify the same database as the role. User-defined roles scoped for the admin database can specify other databases.

**Note:** When you specify a database as the resource, system collections are excluded, unless you name them explicitly, as in the following:

```
{ db: "test", collection: "system.js" }
```

System collections include but are not limited to the following:

- `<database>.system.profile`
- `<database>.system.js`
- `system.users Collection` (page 96) in the admin database
- `system.roles Collection` (page 93) in the admin database

Specify Collections Across Databases as Resource  If only the `db` field is an empty string (""), the resource is all collections with the specified name across all databases. For example, the following document specifies the resource of all the `accounts` collections across all the databases:

```
{ db: "", collection: "accounts" }
```

For user-defined roles, only roles scoped for the admin database can have this resource specification for their privileges.

Specify All Non-System Collections in All Databases  If both the `db` and `collection` fields are empty strings (""), the resource is all collections, excluding the system collections, in all the databases:

```
{ db: ", collection: " " }
```

For user-defined roles, only roles scoped for the admin database can have this resource specification for their privileges.

Cluster Resource

To specify the cluster as the resource, use the following syntax:

```
{ cluster : true }
```

Use the `cluster` resource for actions that affect the state of the system rather than act on specific set of databases or collections. Examples of such actions are `shutdown`, `replSetReconfig`, and `addShard`. For example, the following document grants the action `shutdown` on the cluster.

```
{ resource: { cluster : true }, actions: [ "shutdown" ] }
```

For user-defined roles, only roles scoped for the admin database can have this resource specification for their privileges.
anyResource

The internal resource anyResource gives access to every resource in the system and is intended for internal use. Do not use this resource, other than in exceptional circumstances. The syntax for this resource is { anyResource: true }.

Privilege Actions

New in version 2.6.

Privilege actions define the operations a user can perform on a resource (page 97). A MongoDB privilege (page 14) comprises a resource (page 97) and the permitted actions. This page lists available actions grouped by common purpose.

MongoDB provides built-in roles with pre-defined pairings of resources and permitted actions. For lists of the actions granted, see Built-In Roles (page 85). To define custom roles, see Create a User-Defined Role (page 70).

Query and Write Actions

find
User can perform the db.collection.find() method. Apply this action to database or collection resources.

insert
User can perform the insert command. Apply this action to database or collection resources.

remove
User can perform the db.collection.remove() method. Apply this action to database or collection resources.

update
User can perform the update command. Apply this action to database or collection resources.

Database Management Actions

changeCustomData
User can change the custom information of any user in the given database. Apply this action to database resources.

changeOwnCustomData
Users can change their own custom information. Apply this action to database resources. See also Change Your Password and Custom Data (page 75).

changeOwnPassword
Users can change their own passwords. Apply this action to database resources. See also Change Your Password and Custom Data (page 75).

changePassword
User can change the password of any user in the given database. Apply this action to database resources.

createCollection
User can perform the db.createCollection() method. Apply this action to database or collection resources.
createIndex
Provides access to the `db.collection.createIndex()` method and the `createIndexes` command. Apply this action to database or collection resources.

createRole
User can create new roles in the given database. Apply this action to database resources.

createUser
User can create new users in the given database. Apply this action to database resources.

dropCollection
User can perform the `db.collection.drop()` method. Apply this action to database or collection resources.

dropRole
User can delete any role from the given database. Apply this action to database resources.

dropUser
User can remove any user from the given database. Apply this action to database resources.

eemptycapped
User can perform the `emptycapped` command. Apply this action to database or collection resources.

enableProfiler
User can perform the `db.setProfilingLevel()` method. Apply this action to database resources.

grantRole
User can grant any role in the database to any user from any database in the system. Apply this action to database resources.

killCursors
User can kill cursors on the target collection.

revokeRole
User can remove any role from any user from any database in the system. Apply this action to database resources.

unlock
User can perform the `db.fsyncUnlock()` method. Apply this action to the cluster resource.

viewRole
User can view information about any role in the given database. Apply this action to database resources.

viewUser
User can view the information of any user in the given database. Apply this action to database resources.

Deployment Management Actions

authSchemaUpgrade
User can perform the `authSchemaUpgrade` command. Apply this action to the cluster resource.

cleanupOrphaned
User can perform the `cleanupOrphaned` command. Apply this action to the cluster resource.

cpuProfiler
User can enable and use the CPU profiler. Apply this action to the cluster resource.

inprog
User can use the `db.currentOp()` method to return pending and active operations. Apply this action to the cluster resource.

invalidateUserCache
Provides access to the `invalidateUserCache` command. Apply this action to the cluster resource.
**killop**
User can perform the `db.killOp()` method. Apply this action to the cluster resource.

**planCacheRead**
User can perform the `planCacheListPlans` and `planCacheListQueryShapes` commands and the `PlanCache.getPlansByQuery()` and `PlanCache.listQueryShapes()` methods. Apply this action to database or collection resources.

**planCacheWrite**
User can perform the `planCacheClear` command and the `PlanCache.clear()` and `PlanCache.clearPlansByQuery()` methods. Apply this action to database or collection resources.

**storageDetails**
User can perform the `storageDetails` command. Apply this action to database or collection resources.

**Replication Actions**

**appendOplogNote**
User can append notes to the oplog. Apply this action to the cluster resource.

**replSetConfigure**
User can configure a replica set. Apply this action to the cluster resource.

**replSetGetStatus**
User can perform the `replSetGetStatus` command. Apply this action to the cluster resource.

**replSetHeartbeat**
User can perform the `replSetHeartbeat` command. Apply this action to the cluster resource.

**replSetStateChange**
User can change the state of a replica set through the `replSetFreeze`, `replSetMaintenance`, `replSetStepDown`, and `replSetSyncFrom` commands. Apply this action to the cluster resource.

**resync**
User can perform the `resync` command. Apply this action to the cluster resource.

**Sharding Actions**

**addShard**
User can perform the `addShard` command. Apply this action to the cluster resource.

**enableSharding**
User can enable sharding on a database using the `enableSharding` command and can shard a collection using the `shardCollection` command. Apply this action to database or collection resources.

**flushRouterConfig**
User can perform the `flushRouterConfig` command. Apply this action to the cluster resource.

**getShardMap**
User can perform the `getShardMap` command. Apply this action to the cluster resource.

**getShardVersion**
User can perform the `getShardVersion` command. Apply this action to database resources.

**listShards**
User can perform the `listShards` command. Apply this action to the cluster resource.

**moveChunk**
User can perform the `moveChunk` command. In addition, user can perform the `movePrimary` command
provided that the privilege is applied to an appropriate database resource. Apply this action to database or collection resources.

**removeShard**
User can perform the `removeShard` command. Apply this action to the `cluster` resource.

**shardingState**
User can perform the `shardingState` command. Apply this action to the `cluster` resource.

**splitChunk**
User can perform the `splitChunk` command. Apply this action to database or collection resources.

**splitVector**
User can perform the `splitVector` command. Apply this action to database or collection resources.

**Server Administration Actions**

**applicationMessage**
User can perform the `logApplicationMessage` command. Apply this action to the `cluster` resource.

**closeAllDatabases**
User can perform the `closeAllDatabases` command. Apply this action to the `cluster` resource.

**collMod**
User can perform the `collMod` command. Apply this action to database or collection resources.

**compact**
User can perform the `compact` command. Apply this action to database or collection resources.

**connPoolSync**
User can perform the `connPoolSync` command. Apply this action to the `cluster` resource.

**convertToCapped**
User can perform the `convertToCapped` command. Apply this action to database or collection resources.

**dropDatabase**
User can perform the `dropDatabase` command. Apply this action to database resources.

**dropIndex**
User can perform the `dropIndex` command. Apply this action to database or collection resources.

**fsync**
User can perform the `fsync` command. Apply this action to the `cluster` resource.

**getParameter**
User can perform the `getParameter` command. Apply this action to the `cluster` resource.

**hostInfo**
Provides information about the server the MongoDB instance runs on. Apply this action to the `cluster` resource.

**logRotate**
User can perform the `logRotate` command. Apply this action to the `cluster` resource.

**reIndex**
User can perform the `reIndex` command. Apply this action to database or collection resources.

**renameCollectionSameDB**
Allows the user to rename collections on the current database using the `renameCollection` command. Apply this action to database resources.
Additionally, the user must either have find (page 99) on the source collection or not have find (page 99) on the destination collection.

If a collection with the new name already exists, the user must also have the dropCollection (page 100) action on the destination collection.

**repairDatabase**

User can perform the repairDatabase command. Apply this action to database resources.

**setParameter**

User can perform the setParameter command. Apply this action to the cluster resource.

**shutdown**

User can perform the shutdown command. Apply this action to the cluster resource.

**touch**

User can perform the touch command. Apply this action to the cluster resource.

**Diagnostic Actions**

**collStats**

User can perform the collStats command. Apply this action to database or collection resources.

**connPoolStats**

User can perform the connPoolStats and shardConnPoolStats commands. Apply this action to the cluster resource.

**cursorInfo**

User can perform the cursorInfo command. Apply this action to the cluster resource.

**dbHash**

User can perform the dbHash command. Apply this action to database or collection resources.

**dbStats**

User can perform the dbStats command. Apply this action to database resources.

**diagLogging**

User can perform the diagLogging command. Apply this action to the cluster resource.

**getCmdLineOpts**

User can perform the getCmdLineOpts command. Apply this action to the cluster resource.

**getLog**

User can perform the getLog command. Apply this action to the cluster resource.

**indexStats**

User can perform the indexStats command. Apply this action to database or collection resources.

**listDatabases**

User can perform the listDatabases command. Apply this action to the cluster resource.

**listCollections**

User can perform the listCollections command. Apply this action to database resources.

**listIndexes**

User can perform the ListIndexes command. Apply this action to database or collection resources.

**netstat**

User can perform the netstat command. Apply this action to the cluster resource.

**serverStatus**

User can perform the serverStatus command. Apply this action to the cluster resource.
**validate**
User can perform the validate command. Apply this action to database or collection resources.

**top**
User can perform the top command. Apply this action to the cluster resource.

**Internal Actions**

**anyAction**
Allows any action on a resource. **Do not** assign this action except for exceptional circumstances.

**internal**
Allows internal actions. **Do not** assign this action except for exceptional circumstances.

---

**Default MongoDB Port**

The following table lists the default ports used by MongoDB:

<table>
<thead>
<tr>
<th>Default Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>27017</td>
<td>The default port for mongod and mongos instances. You can change this port with port or --port.</td>
</tr>
<tr>
<td>27018</td>
<td>The default port when running with --shardsvr runtime operation or the shardsvr value for the clusterRole setting in a configuration file.</td>
</tr>
<tr>
<td>27019</td>
<td>The default port when running with --configsvr runtime operation or the configsvr value for the clusterRole setting in a configuration file.</td>
</tr>
<tr>
<td>28017</td>
<td>The default port for the web status page. The web status page is always accessible at a port number that is 1000 greater than the port determined by port.</td>
</tr>
</tbody>
</table>

---

**System Event Audit Messages**

**Note:** Available only in MongoDB Enterprise⁹².

---

**Audit Message**

The `event auditing feature` (page 16) can record events in JSON format. To configure auditing output, see `Configure System Events Auditing` (page 78)

The recorded JSON messages have the following syntax:

```json
{
  atype: <String>,
  ts : { "$date": <timestamp> },
  local: { ip: <String>, port: <int> },
  remote: { ip: <String>, port: <int> },
  users : [ { user: <String>, db: <String> }, ... ],
  roles: [ { role: <String>, db: <String> }, ... ],
  param: <document>,
  result: <int>
}
```

field String atype  Action type. See Audit Event Actions, Details, and Results (page 105).
field document ts  Document that contains the date and UTC time of the event, in ISO 8601 format.
field document local  Document that contains the local ip address and the port number of the running instance.
field document remote  Document that contains the remote ip address and the port number of the incoming connection associated with the event.
field array users  Array of user identification documents. Because MongoDB allows a session to log in with different user per database, this array can have more than one user. Each document contains a user field for the username and a db field for the authentication database for that user.
field array roles  Array of documents that specify the roles (page 14) granted to the user. Each document contains a role field for the name of the role and a db field for the database associated with the role.
field document param  Specific details for the event. See Audit Event Actions, Details, and Results (page 105).
field integer result  Error code. See Audit Event Actions, Details, and Results (page 105).

Audit Event Actions, Details, and Results

The following table lists for each atype or action type, the associated param details and the result values, if any.

<table>
<thead>
<tr>
<th>atype</th>
<th>param</th>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>authenticate</td>
<td>{</td>
<td>0 - Success</td>
</tr>
<tr>
<td></td>
<td>user: &lt;user name&gt;,</td>

4.3 Security Release Notes Alerts

Security Release Notes

Access to system.users Collection

Changed in version 2.4.
In 2.4, only users with the userAdmin role have access to the system.users collection.
In version 2.2 and earlier, the read-write users of a database all have access to the system.users collection, which contains the user names and user password hashes. 94

Password Hashing Insecurity

If a user has the same password for multiple databases, the hash will be the same. A malicious user could exploit this to gain access on a second database using a different user’s credentials.
As a result, always use unique username and password combinations for each database.
Thanks to Will Urbanski, from Dell SecureWorks, for identifying this issue.

5 Security Checklist

This documents provides a list of security measures that you should implement to protect your MongoDB installation.

5.1 Require Authentication

Enable MongoDB authentication and specify the authentication mechanism. You can use the MongoDB authentication mechanism or an existing external framework. Authentication requires that all clients and servers provide valid credentials before they can connect to the system. In clustered deployments, enable authentication for each MongoDB server.
See Authentication (page 6), Enable Client Access Control (page 40), and Enable Authentication in a Sharded Cluster (page 41).

94 Read-only users do not have access to the system.users collection.
5.2 Configure Role-Based Access Control

Create a user administrator first, then create additional users. Create a unique MongoDB user for each person and application that accesses the system.

Create roles that define the exact access a set of users needs. Follow a principle of least privilege. Then create users and assign them only the roles they need to perform their operations. A user can be a person or a client application.

See Authorization (page 14), Create a User Administrator (page 67), and Manage User and Roles (page 69).

5.3 Encrypt Communication

Configure MongoDB to use TLS/SSL for all incoming and outgoing connections. Use TLS/SSL to encrypt communication between mongod and mongos components of a MongoDB client as well as between all applications and MongoDB.

See Configure mongod and mongos for TLS/SSL (page 26).

5.4 Limit Network Exposure

Ensure that MongoDB runs in a trusted network environment and limit the interfaces on which MongoDB instances listen for incoming connections. Allow only trusted clients to access the network interfaces and ports on which MongoDB instances are available.

See the bindIp setting, and see Configure Linux iptables Firewall for MongoDB (page 19) and Configure Windows netsh Firewall for MongoDB (page 23).

5.5 Audit System Activity

Track access and changes to database configurations and data. MongoDB Enterprise95 includes a system auditing facility that can record system events (e.g. user operations, connection events) on a MongoDB instance. These audit records permit forensic analysis and allow administrators to verify proper controls.

See Auditing (page 16) and Configure System Events Auditing (page 78).

5.6 Encrypt and Protect Data

Encrypt MongoDB data on each host using file-system, device, or physical encryption. Protect MongoDB data using file-system permissions. MongoDB data includes data files, configuration files, auditing logs, and key files.

5.7 Run MongoDB with a Dedicated User

Run MongoDB processes with a dedicated operating system user account. Ensure that the account has permissions to access data but no unnecessary permissions.

See http://docs.mongodb.org/manual/installation for more information on running MongoDB.

95http://www.mongodb.com/products/mongodb-enterprise?jmp=docs
5.8 Run MongoDB with Secure Configuration Options

MongoDB supports the execution of JavaScript code for certain server-side operations: mapReduce, group, and $where. If you do not use these operations, disable server-side scripting by using the --noscripting option on the command line.

Use only the MongoDB wire protocol on production deployments. Do not enable the following, all of which enable the web server interface: enabled.net.http.JSONPEnabled, and net.http.RESTInterfaceEnabled. Leave these disabled, unless required for backwards compatibility.

Keep input validation enabled. MongoDB enables input validation by default through the wireObjectCheck setting. This ensures that all documents stored by the mongod instance are valid BSON.

5.9 Request a Security Technical Implementation Guide (where applicable)

The Security Technical Implementation Guide (STIG) contains security guidelines for deployments within the United States Department of Defense. MongoDB Inc. provides its STIG, upon request, for situations where it is required. Please request a copy for more information.

5.10 Consider Security Standards Compliance

For applications requiring HIPAA or PCI-DSS compliance, please refer to the MongoDB Security Reference Architecture to learn more about how you can use the key security capabilities to build compliant application infrastructure.
